## **Abstract**

This document describes the different features and utilities that make Red Hat Enterprise Linux 6 an ideal enterprise platform for application development. It focuses on Eclipse as an end-to-end integrated development environment (IDE), but also includes command line tools and other utilities outside Eclipse.

## Table of Contents

<b>Chapter 1. Eclipse Development Environment .....</b>	<b>6</b>
1.1. Starting an Eclipse project	6
1.2. Eclipse User Interface	9
1.2.1. The Quick Access Menu	14
1.2.2. Keyboard Shortcuts	15
1.2.3. Customize Perspective	17
1.3. Editing C/C++ Source Code in Eclipse	20
1.3.1. libhover Plug-in	21
1.3.1.1. Setup and Usage	22
1.4. Editing Java Source Code in Eclipse	24
1.5. Eclipse RPM Building	25
1.6. Eclipse Documentation	26
<b>Chapter 2. Collaborating .....</b>	<b>29</b>
2.1. Concurrent Versions System (CVS)	29
2.1.1. Installing and Configuring CVS	29
Installing the cvs Package	29
Setting Up the Default Editor	29
2.1.2. Creating a New Repository	30
Initializing an Empty Repository	30
Importing Data to a Repository	30
2.1.3. Checking Out a Working Copy	31
2.1.4. Adding and Deleting Files	31
Adding a File	31
Deleting a File	32
2.1.5. Viewing Changes	33
Viewing the Status	33
Viewing Differences	33
2.1.6. Committing Changes	34
2.1.7. Updating a Working Copy	35
2.1.8. Additional Resources	35
Installed Documentation	35
2.2. Apache Subversion (SVN)	36
2.2.1. Installing and Configuring Subversion	36
Installing the subversion Package	36
Setting Up the Default Editor	36
2.2.2. Creating a New Repository	36
Initializing an Empty Repository	37
Importing Data to a Repository	37
2.2.3. Checking Out a Working Copy	38
2.2.4. Adding, Renaming, and Deleting Files	38
Adding a File or Directory	38
Renaming a File or Directory	39
Deleting a File or Directory	39
2.2.5. Viewing Changes	40
Viewing the Status	40
Viewing Differences	41
2.2.6. Committing Changes	41
2.2.7. Updating a Working Copy	42
2.2.8. Additional Resources	43
Installed Documentation	43
Online Documentation	43

	Online Documentation	43
2.3.	Git	43
2.3.1.	Installing and Configuring Git	43
	Installing the git Package	43
	Configuring the Default Text Editor	43
	Setting Up User Information	44
2.3.2.	Creating a New Repository	44
	Initializing an Empty Repository	44
	Importing Data to a Repository	44
2.3.3.	Cloning an Existing Repository	45
2.3.4.	Adding, Renaming, and Deleting Files	45
	Adding Files and Directories	45
	Renaming Files and Directories	45
	Deleting Files and Directories	46
2.3.5.	Viewing Changes	46
	Viewing the Current Status	46
	Viewing Differences	46
2.3.6.	Committing Changes	46
2.3.7.	Sharing Changes	47
	Pushing Changes to a Public Repository	47
	Creating Patches from Individual Commits	47
2.3.8.	Updating a Repository	47
2.3.9.	Additional Resources	48
	Installed Documentation	48
	Online Documentation	48
<b>Chapter 3.</b>	<b>Libraries and Runtime Support</b>	<b>49</b>
3.1.	Version Information	49
3.2.	Compatibility	50
3.2.1.	Static Linking	50
3.3.	Library and Runtime Details	51
3.3.1.	compat-glibc	51
3.3.2.	The GNU C++ Standard Library	51
3.3.2.1.	GNU C++ Standard Library Updates	51
3.3.2.2.	GNU C++ Standard Library Documentation	53
3.3.3.	Boost	53
3.3.3.1.	Boost Updates	55
3.3.3.2.	Boost Documentation	56
3.3.4.	Qt	56
3.3.4.1.	Qt Updates	56
3.3.4.2.	Qt Creator	57
3.3.4.3.	Qt Library Documentation	57
3.3.5.	KDE Development Framework	57
3.3.5.1.	KDE4 Architecture	57
3.3.5.2.	kdelibs Documentation	59
3.3.6.	GNOME Power Manager	59
3.3.6.1.	GNOME Power Management Version Guide	59
3.3.6.2.	API Changes for glib	60
3.3.6.3.	API Changes for GTK+	61
3.3.7.	NSS Shared Databases	62
3.3.7.1.	Backwards Compatibility	62
3.3.7.2.	NSS Shared Databases Documentation	63
3.3.8.	Python	63
3.3.8.1.	Python Updates	63

3.3.8.2. Python Documentation	63
3.3.9. Java	64
3.3.9.1. Java Documentation	64
3.3.10. Ruby	64
3.3.10.1. Ruby Documentation	65
3.3.11. Perl	65
3.3.11.1. Perl Updates	65
3.3.11.2. Installation	67
3.3.11.3. Perl Documentation	68
<b>Chapter 4. Compiling and Building .....</b>	<b>70</b>
4.1. GNU Compiler Collection (GCC)	70
4.1.1. GCC Status and Features	70
4.1.2. Language Compatibility	71
4.1.3. Object Compatibility and Interoperability	73
4.1.4. Backwards Compatibility Packages	73
4.1.5. Previewing Red Hat Enterprise Linux 6 compiler features on Red Hat Enterprise Linux 5	
4.1.6. Running GCC	74
4.1.6.1. Simple C Usage	75
4.1.6.2. Simple C++ Usage	75
4.1.6.3. Simple Multi-File Usage	76
4.1.6.4. Recommended Optimization Options	77
4.1.6.5. Using Profile Feedback to Tune Optimization Heuristics	78
4.1.6.6. Using 32-bit compilers on a 64-bit host	79
4.1.7. GCC Documentation	81
4.2. Distributed Compiling	81
4.3. Autotools	81
4.3.1. Autotools Plug-in for Eclipse	82
4.3.2. Configuration Script	82
4.3.3. Autotools Documentation	83
4.4. Eclipse Built-in Specfile Editor	83
4.5. CDT in Eclipse	83
4.5.1. Managed Make Project	83
4.5.2. Standard Make Project	84
4.5.3. Autotools Project	84
4.6. build-id Unique Identification of Binaries	85
4.7. Software Collections and scl-utils	85
<b>Chapter 5. Debugging .....</b>	<b>87</b>

<b>Index</b> .....	<b>141</b>

# Chapter 1. Eclipse Development Environment

Eclipse is a powerful development environment that provides tools for each phase of the development process. It is integrated into a single, fully configurable user interface for ease of use, featuring a pluggable architecture which allows for extension in a variety of ways.

Eclipse integrates a variety of disparate tools into a unified environment to create a rich development experience. The Valgrind plug-in, for example, allows programmers to perform memory profiling (normally done through the command line) through the Eclipse user interface. This functionality is not exclusive to Eclipse.

Being a graphical application, Eclipse is a welcome alternative for developers who find the command line interface intimidating or difficult. In addition, Eclipse's built-in **Help** system provides extensive documentation for each integrated feature and tool. This greatly decreases the initial time investment required for new developers to become fluent in its use.

The traditional (that is, mostly command line based) Linux tools suite (**gcc**, **gdb**, etc) and Eclipse offer two distinct approaches to programming. Most traditional Linux tools are far more flexible, subtle, and (in aggregate) more powerful than their Eclipse-based counterparts. These traditional Linux tools, on the other hand, are more difficult to master, and offer more capabilities than are required by most programmers or projects. Eclipse, by contrast, sacrifices some of these benefits in favor of an integrated environment, which in turn is suitable for users who prefer their tools accessible in a single, graphical interface.

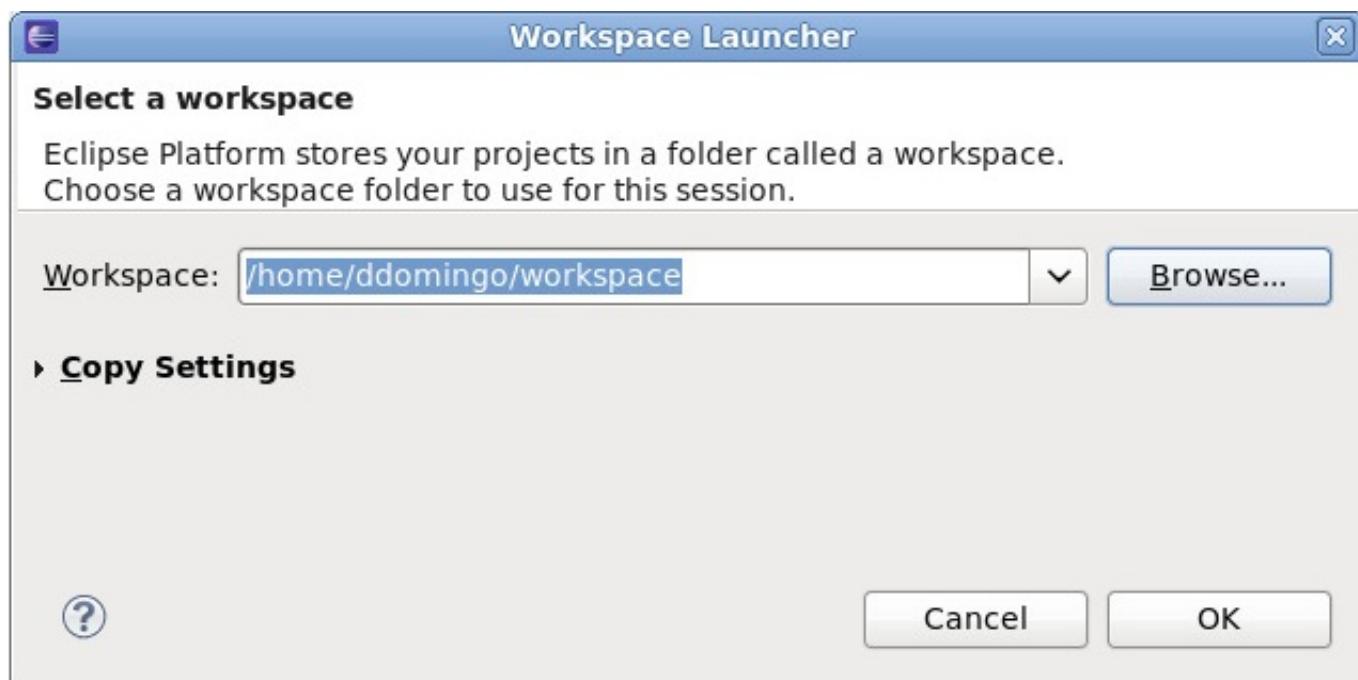

## 1.1. Starting an Eclipse project

Install eclipse with the following command:

```
# yum install eclipse
```

Once installed, Eclipse can be started either by manually executing **/usr/bin/eclipse** or by using the system menu that was created during installation.

Eclipse stores all project and user files in a designated *workspace*. You can have multiple workspaces and can switch between each one on the fly. However, Eclipse will only be able to load projects from the current active workspace. To switch between active workspaces, navigate to **File > Switch Workspace > /path/to/workspace**. You can also add a new workspace through the **Workspace Launcher** wizard; to open this wizard, navigate to **File > Switch Workspace > Other**.

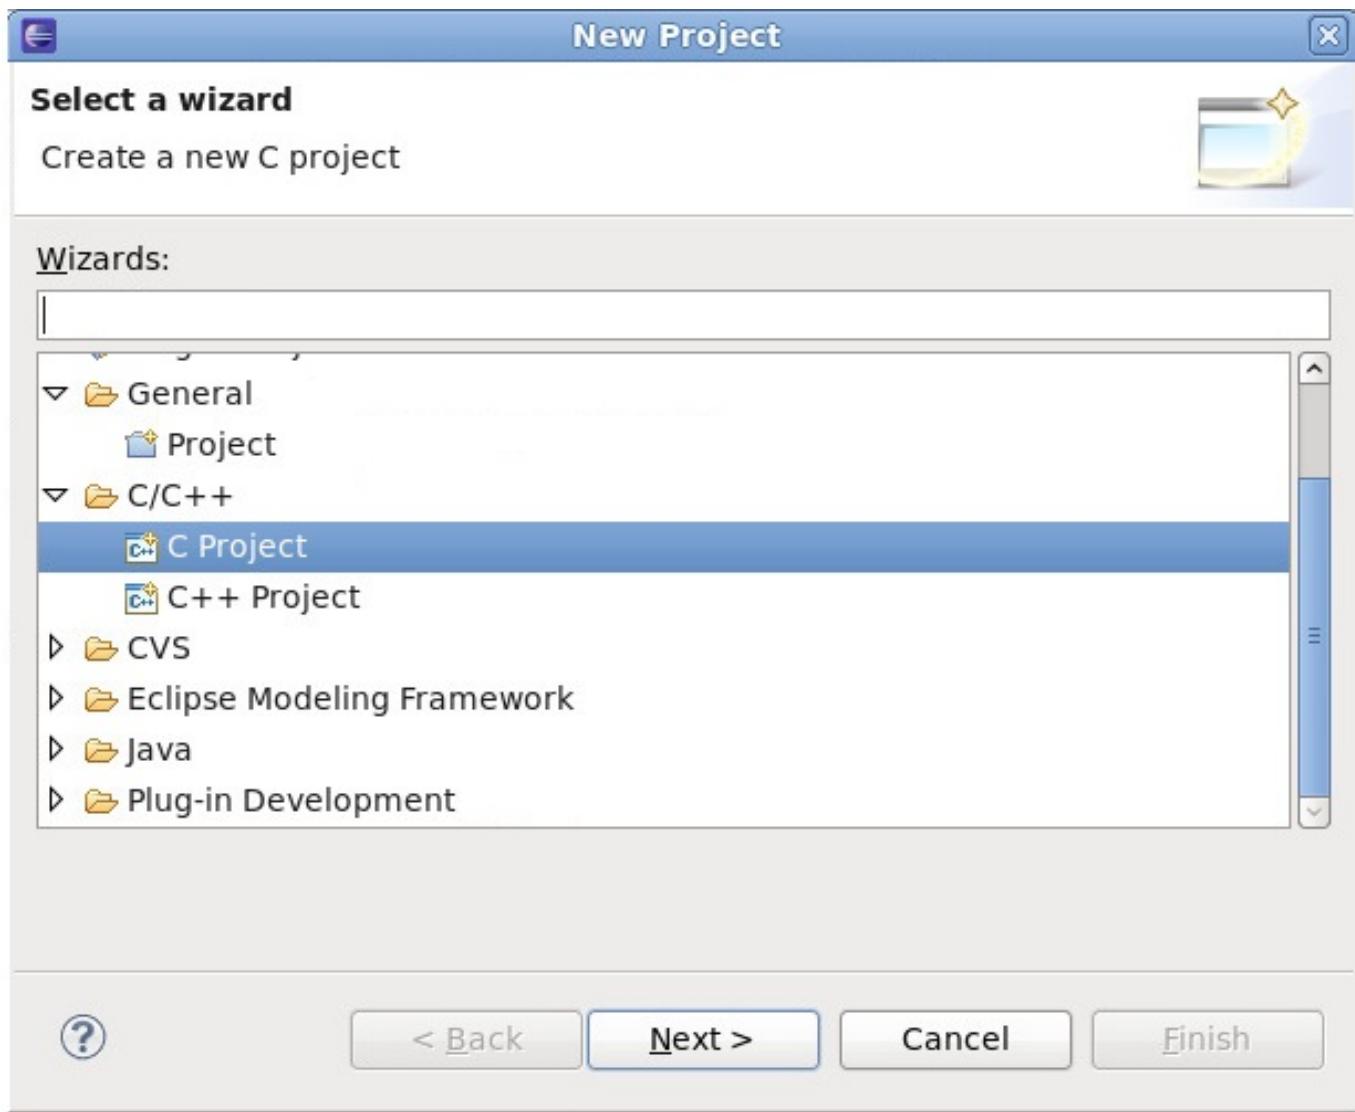

**Figure 1.1. Workspace Launcher**

For information about configuring workspaces, see *Reference > Preferences > Workspace* in the *Workbench User Guide (Help Contents)*.

A project can be imported directly into Eclipse if it contains the necessary Eclipse metafiles. Eclipse uses these files to determine what kind of perspectives, tools, and other user interface configurations to implement.

As such, when attempting to import a project that has never been used on Eclipse, it may be necessary to do so through the **New Project** wizard instead of the **Import** wizard. Doing so will create the necessary Eclipse metafiles for the project, which you can also include when you commit the project.

**Figure 1.2. New Project Wizard**

The **Import** wizard is suitable mostly for projects that were created or previously edited in Eclipse, that is, projects that contain the necessary Eclipse metafiles.

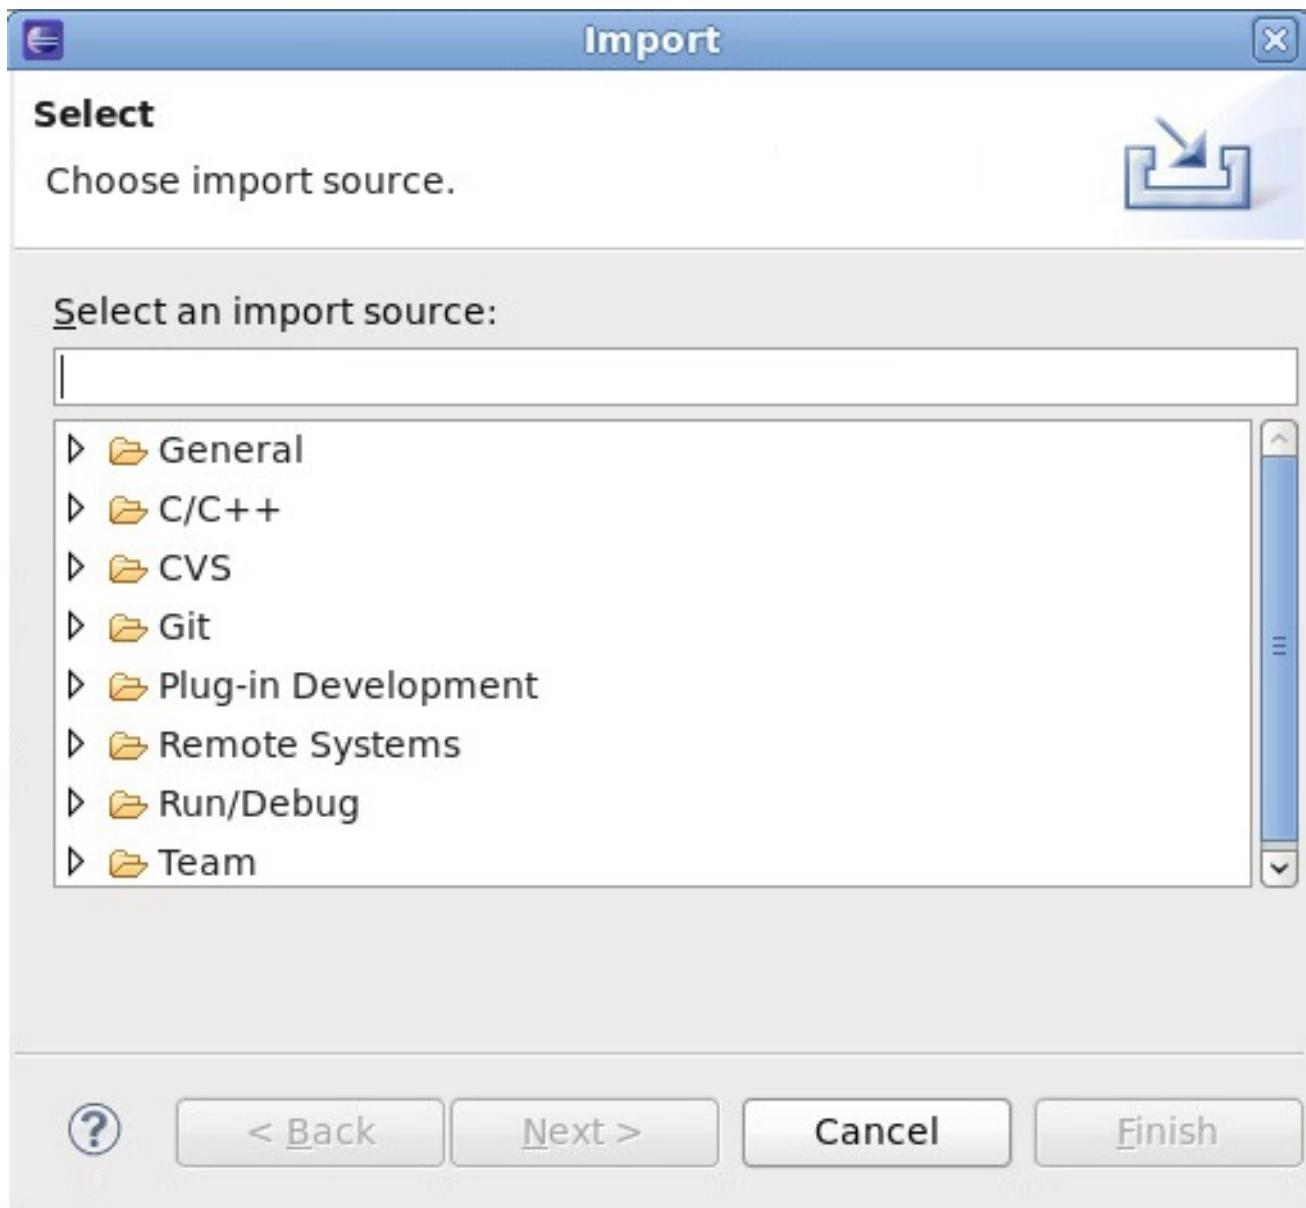

Figure 1.3. Import Wizard

## 1.2. Eclipse User Interface

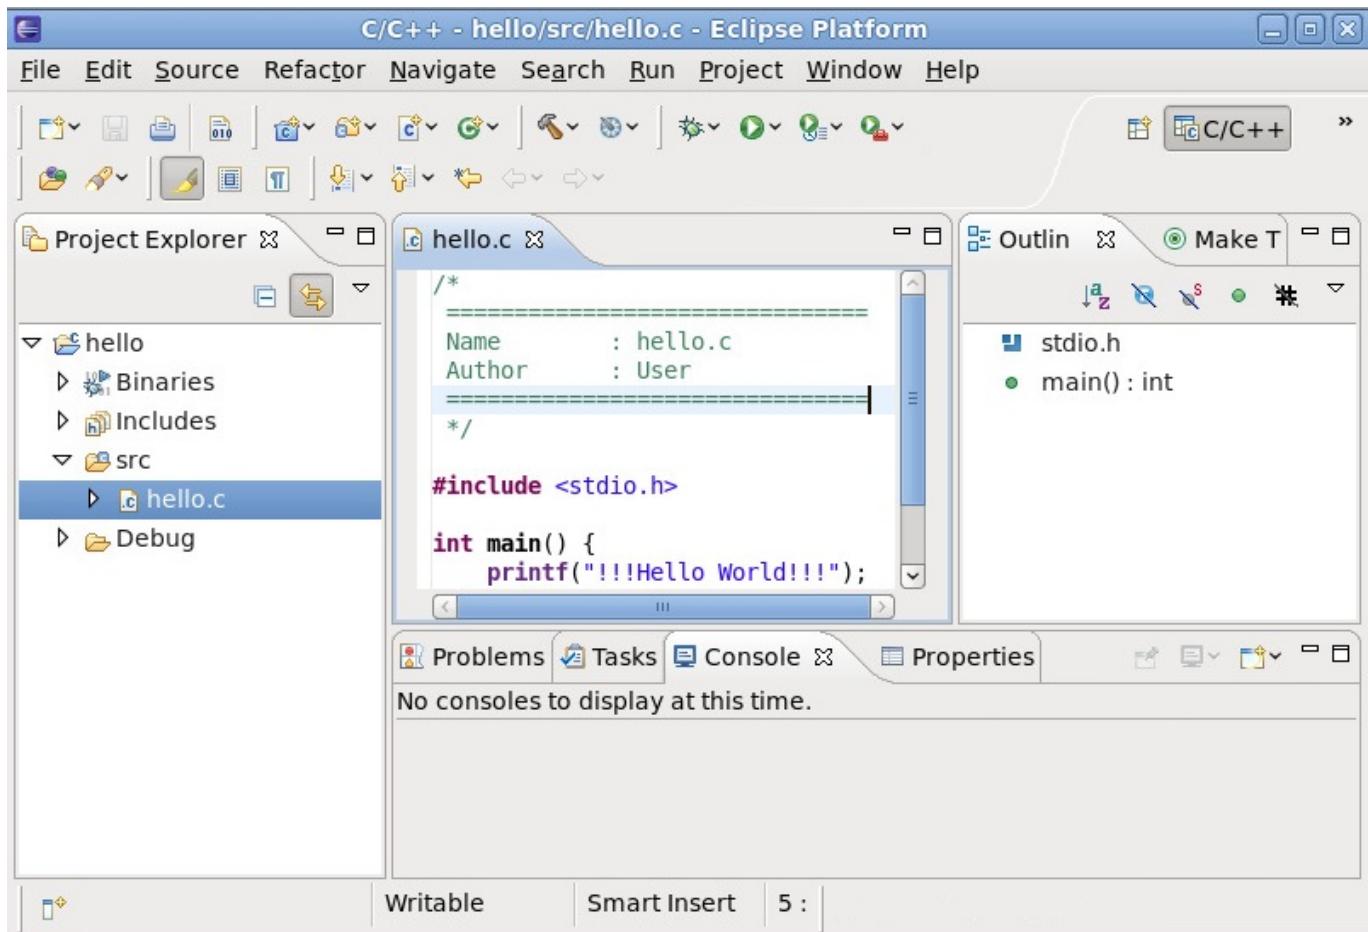

The entire user interface in [Figure 1.4, “Eclipse User Interface \(default\)”](#) is referred to as the Eclipse *workbench*. It is generally composed of a code **Editor**, **Project Explorer** window, and several views. All elements in the Eclipse workbench are configurable, and fully documented in the *Workbench User Guide (Help Contents)*. See [Section 1.2.3, “Customize Perspective”](#) for a brief overview of how to customize the user interface.

Eclipse features different *perspectives*. A perspective is a set of views and editors most useful to a specific type of task or project; the Eclipse workbench can contain one or more perspectives. [Figure 1.4, “Eclipse User Interface \(default\)”](#) features the default perspective for C/C++.

Eclipse also divides many functions into several classes, housed inside distinct *menu items*. For example, the **Project** menu houses functions relating to compiling/building a project. The **Window** menu contains options for creating and customizing perspectives, menu items, and other user interface elements. For a brief overview of each main menu item, see **Reference** → **C/C++ Menubar** in the *C/C++ Development User Guide* or **Reference** → **Menus and Actions** in the *Java Development User Guide*. These are found in the Eclipse help.

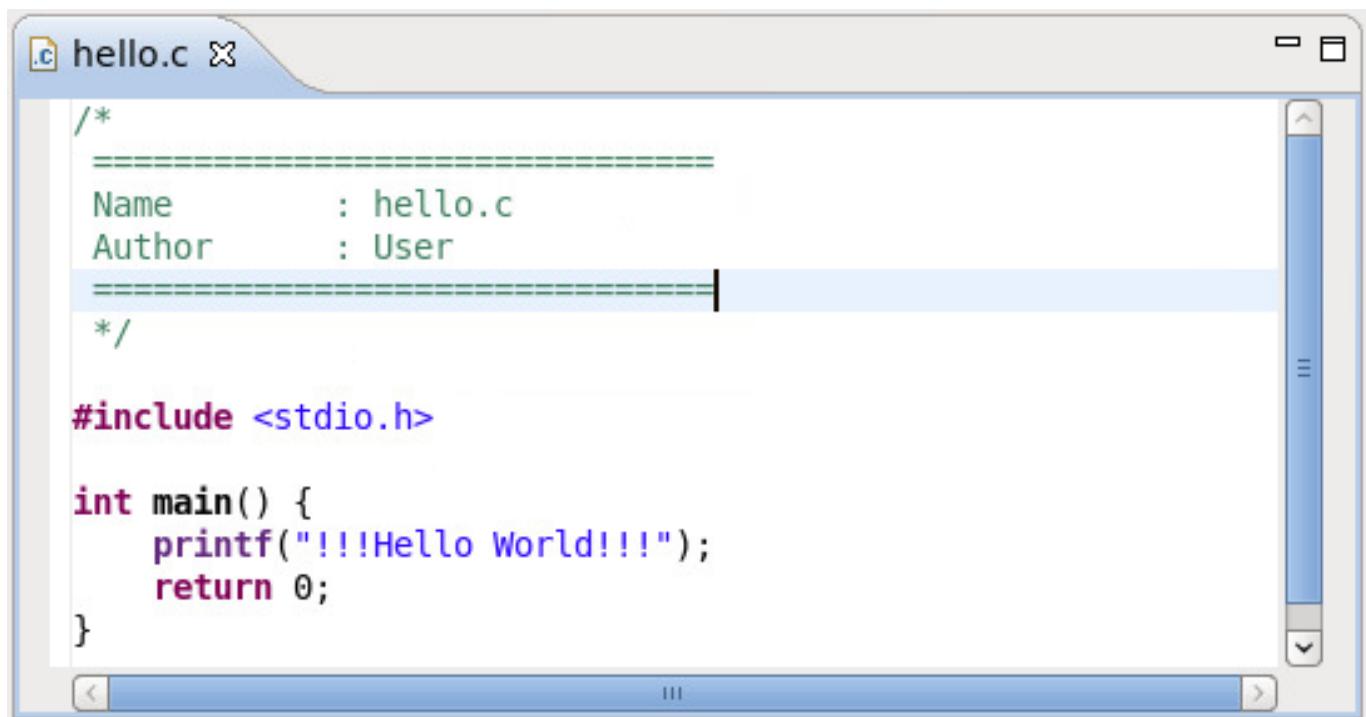

The following sections provide a high-level overview of the different elements visible in the default user interface of the Eclipse *integrated development environment* (IDE).

The Eclipse workbench provides a user interface for many features and tools essential for every phase of the development process. This section provides an overview of Eclipse's primary user interface.

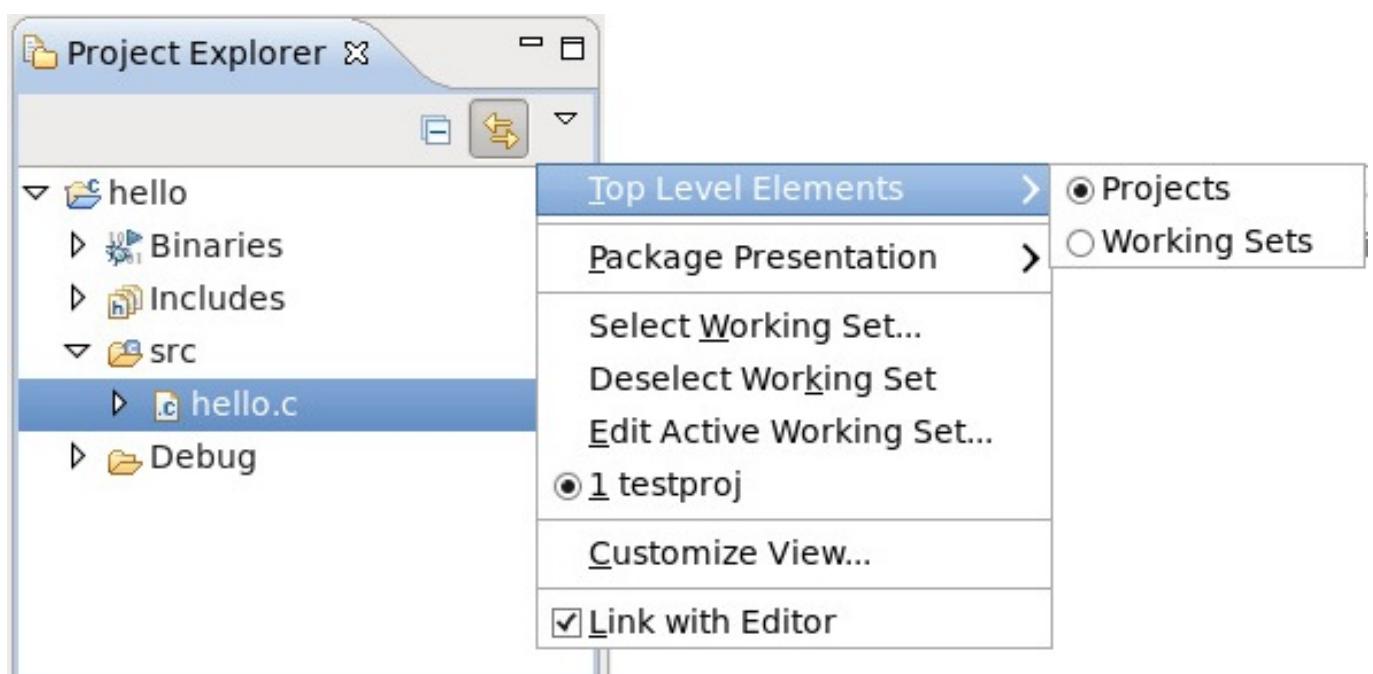

**Figure 1.4. Eclipse User Interface (default)**

[Figure 1.4, “Eclipse User Interface \(default\)”](#) displays the default workbench for C/C++ projects. To switch between available perspectives in a workbench, press **Ctrl+F8**. For some hints on perspective customization, see [Section 1.2.3, “Customize Perspective”](#). The figures that follow describe each basic element visible in the default C/C++ perspective.

**Figure 1.5. Eclipse Editor**

The **Editor** is used to write and edit source files. Eclipse can auto-detect and load an appropriate language editor (for example, C Editor for files ending in `.c`) for most types of source files. To configure the settings for the **Editor**, navigate to **Window > Preferences > language (for example, Java, C++) > Code Style**.

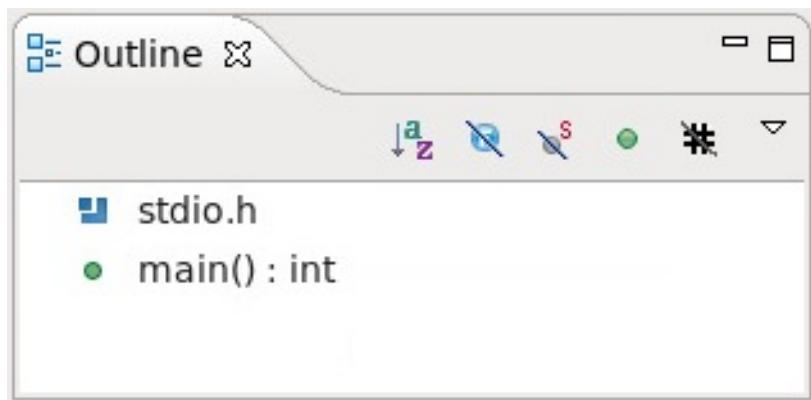

**Figure 1.6. Project Explorer**

The **Project Explorer View** provides a hierarchical view of all project resources (binaries, source files, etc.). You can open, delete, or otherwise edit any files from this view.

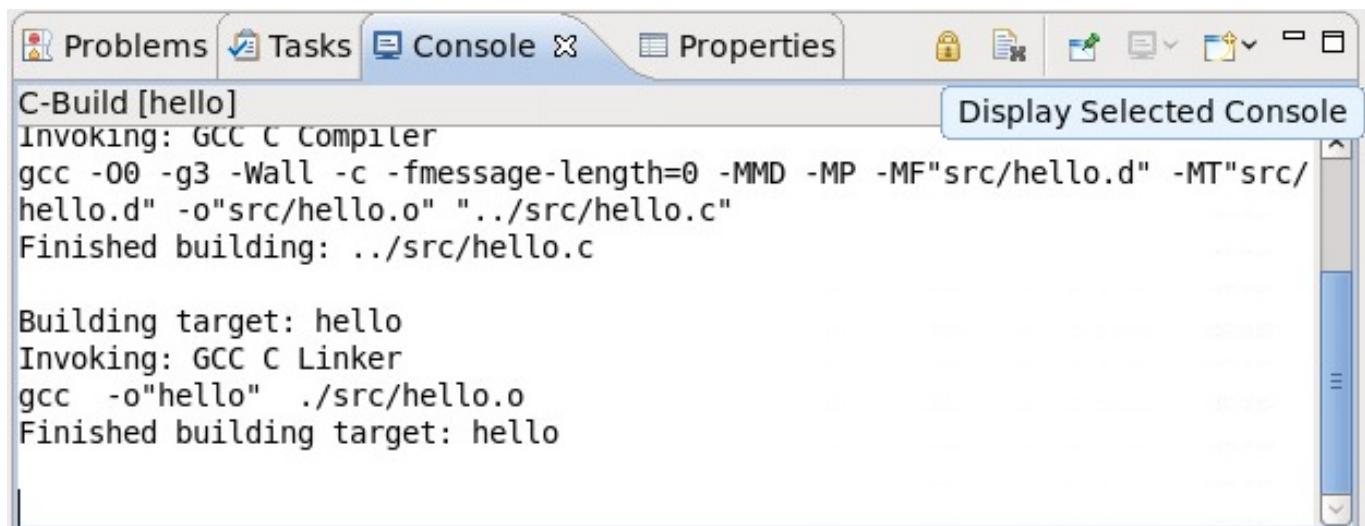

The **View Menu** button in the **Project Explorer View** allows you to configure whether projects or working sets are the top-level items in the **Project Explorer View**. A working set is a group of

projects arbitrarily classified as a single set; working sets are handy in organizing related or linked projects.

**Figure 1.7. Outline Window**

The **Outline** window provides a condensed view of the code in a source file. It details different variables, functions, libraries, and other structural elements from the selected file in the **Editor**, all of which are editor-specific.

**Figure 1.8. Console View**

Some functions and plugged-in programs in Eclipse send their output to the **Console** view. This view's **Display Selected Console** button allows you to switch between different consoles.

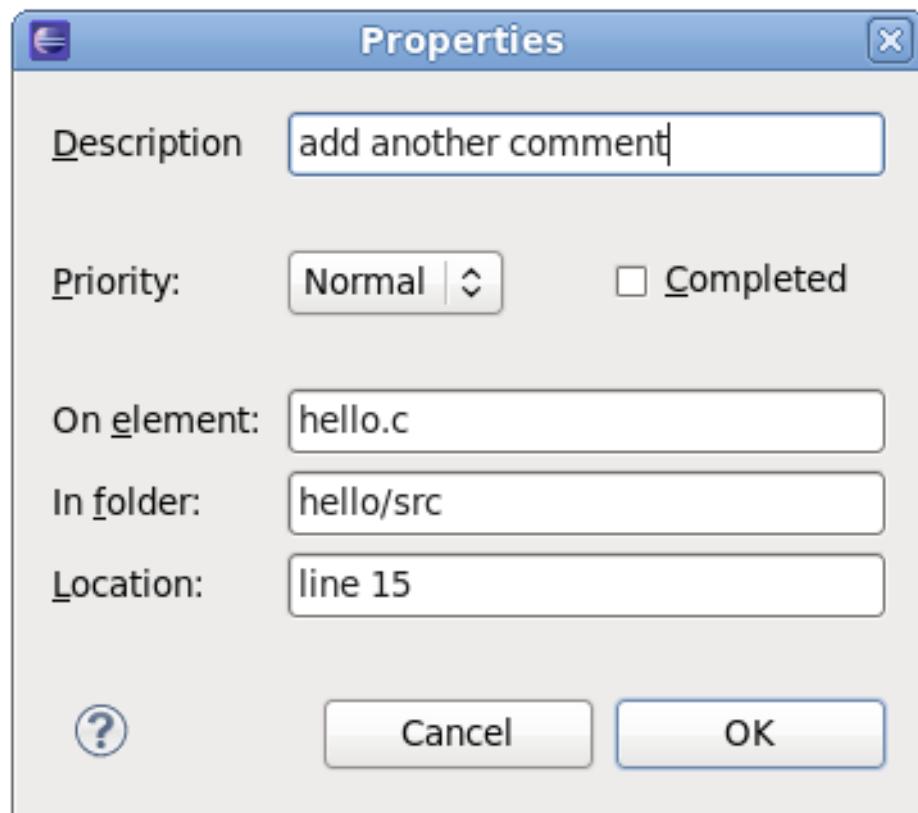

Figure 1.9. Tasks View

The **Tasks** view allows you to track specially-marked reminder comments in the code. This view shows the location of each task comment and allows you to sort them in several ways.

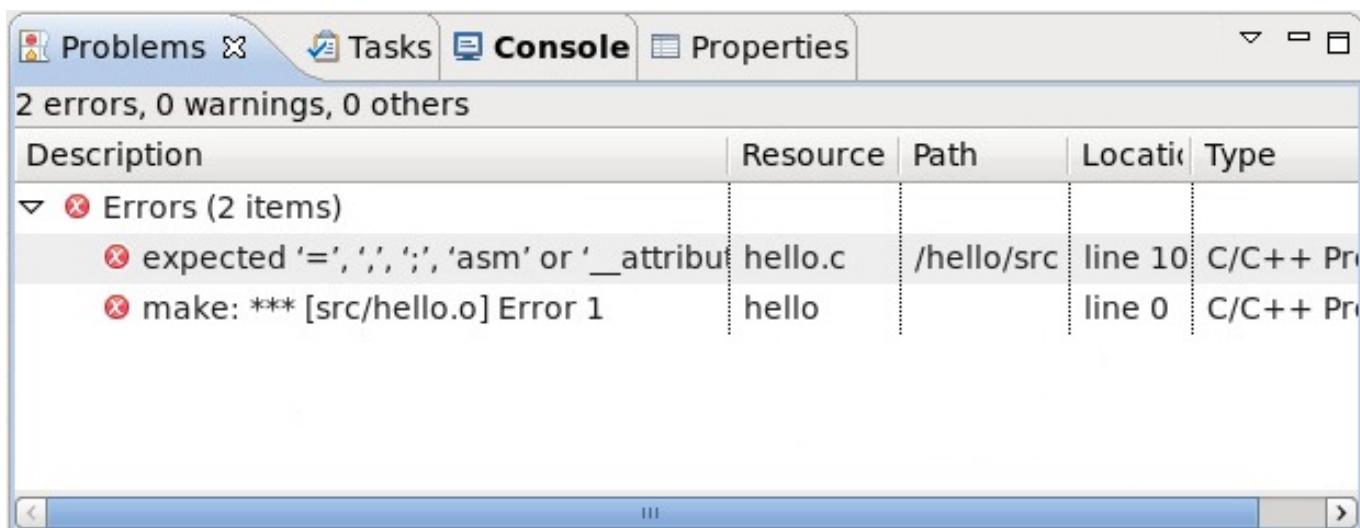

Figure 1.10. Sample of Tracked Comment

Most Eclipse editors track comments marked with `//FIXME` or `//TODO` tags. Tracked comments—that is, *task tags*—are different for source files written in other languages. To add or configure task tags, navigate to **Window > Preferences** and use the keyword **task tags** to display the task tag configuration menus for specific editors/languages.

**Figure 1.11. Task Properties**

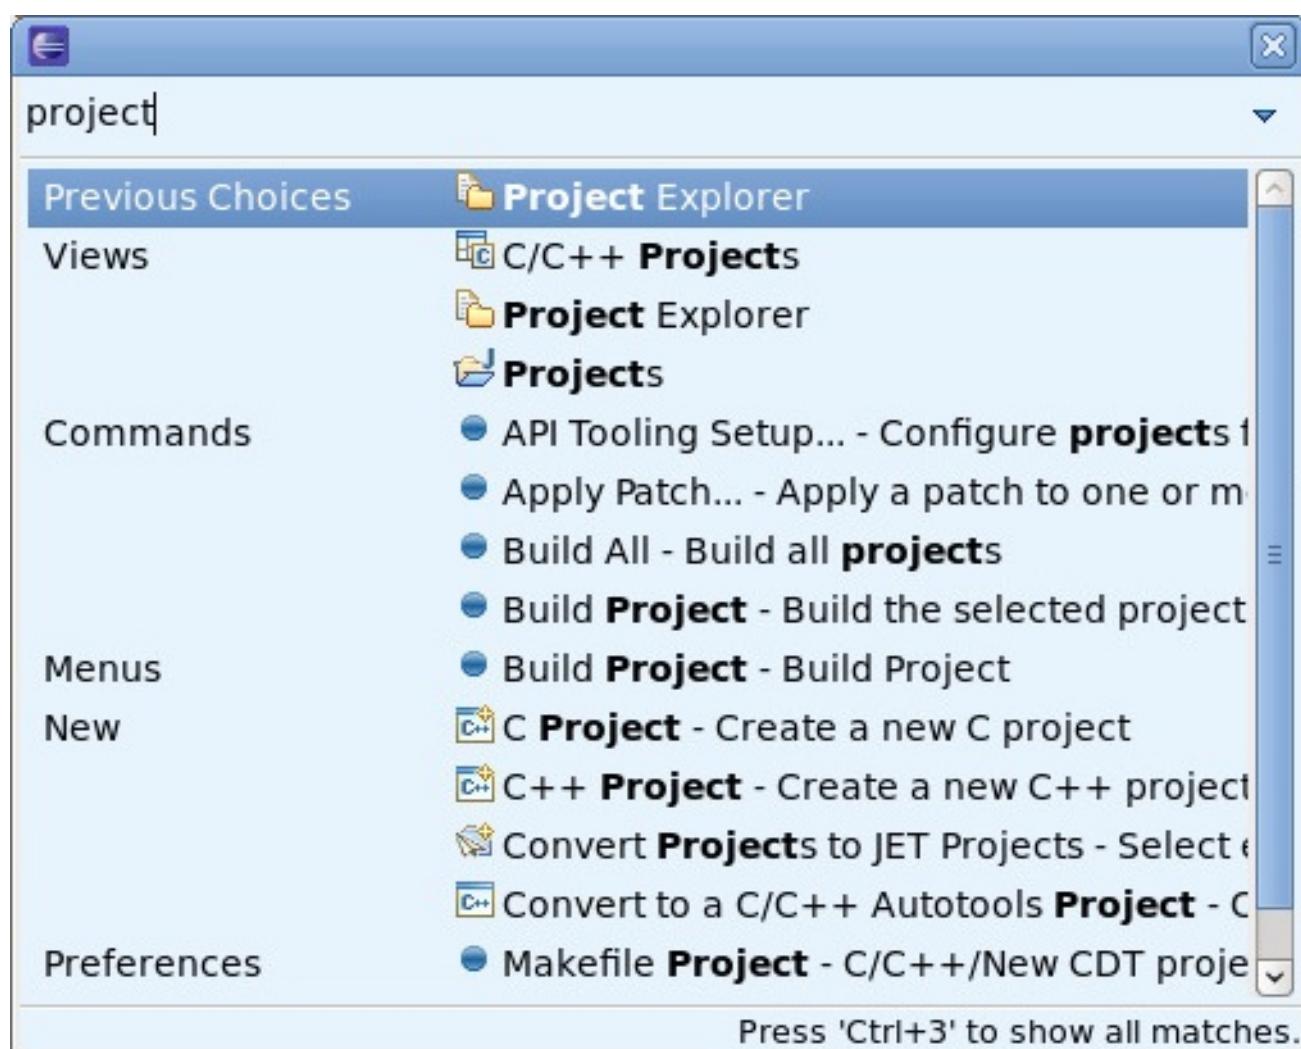

Alternatively, you can also use **Edit > Add Task** to open the task **Properties** menu ([Figure 1.11, "Task Properties"](#)). This will allow you to add a task to a specific location in a source file without using a task tag.

**Figure 1.12. Problems View**

The **Problems** view displays any errors or warnings that occurred during the execution of specific actions such as builds, cleans, or profile runs. To display a suggested "quick fix" to a specific problem, select it and press **Ctrl+1**.

### 1.2.1. The Quick Access Menu

One of the most useful Eclipse tips is to use the **quick access** menu. Typing a word in the **quick access** menu will present a list of Views, Commands, Help files and other actions related to that word. To open this menu, press **Ctrl+3**.

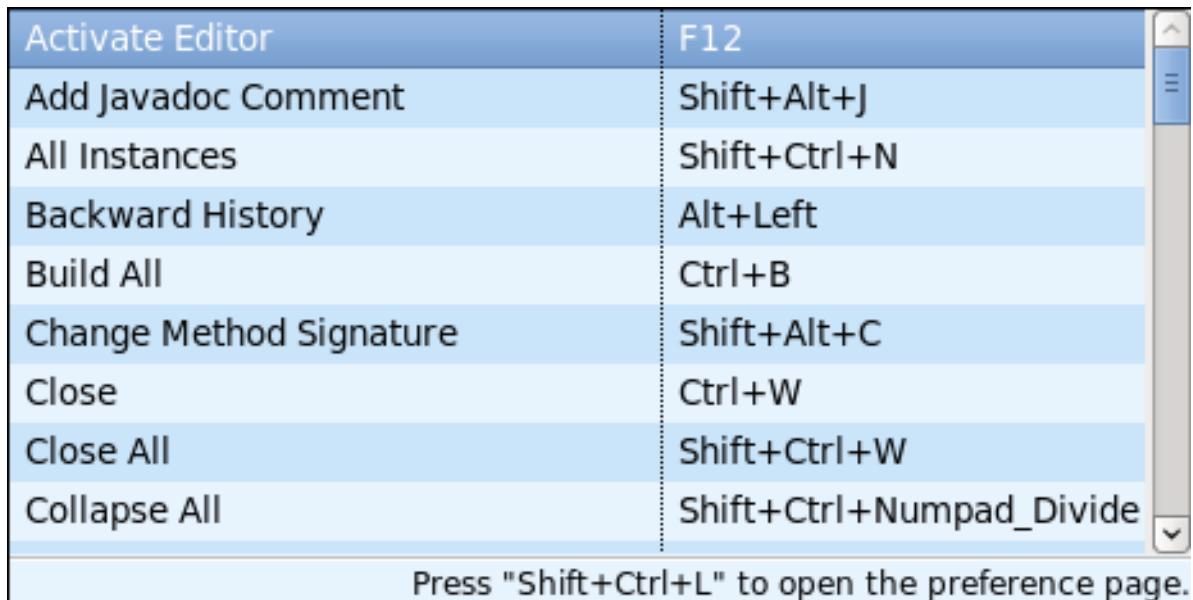

**Figure 1.13. Quick Access Menu**

In [Figure 1.13, “Quick Access Menu”](#), clicking **Views > Project Explorer** will select the **Project Explorer** window. Click any item from the **Commands**, **Menus**, **New**, or **Preferences** categories to run the selected item. This is similar to navigating to or clicking the respective menu options or taskbar icons. You can also navigate through the **quick access** menu using the arrow keys.

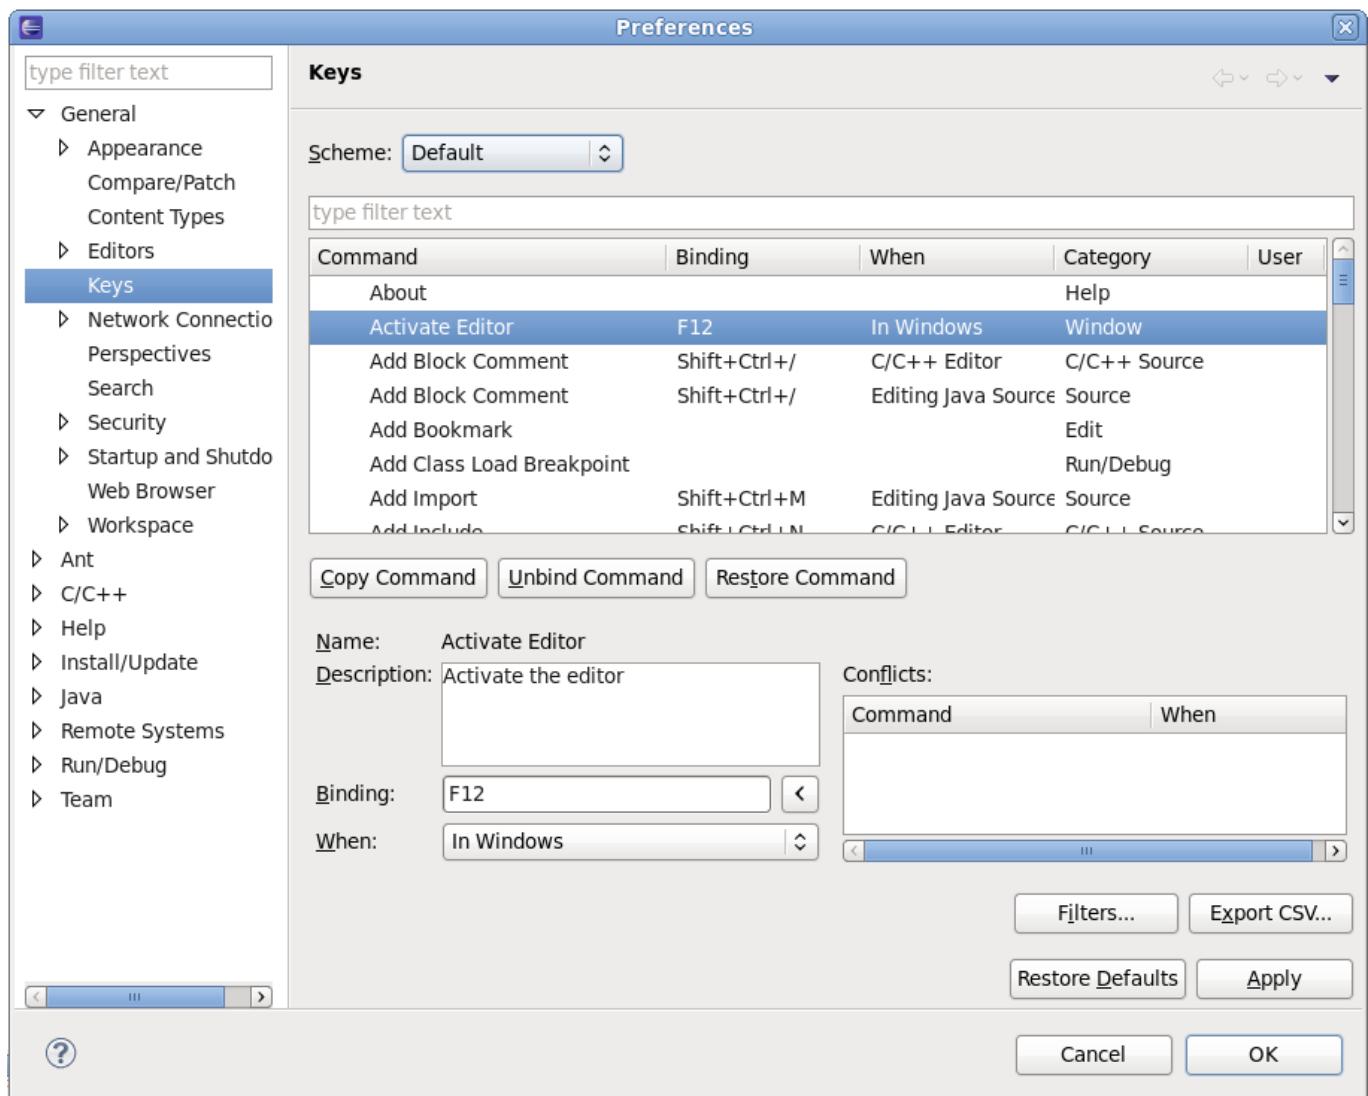

### 1.2.2. Keyboard Shortcuts

It is also possible to view a complete list of all keyboard shortcut commands; to do so, press **Shift+Ctrl+L**.

**Figure 1.14. Keyboard Shortcuts**

To configure Eclipse keyboard shortcuts, press **Shift+Ctrl+L** again while the **Keyboard Shortcuts** list is open.

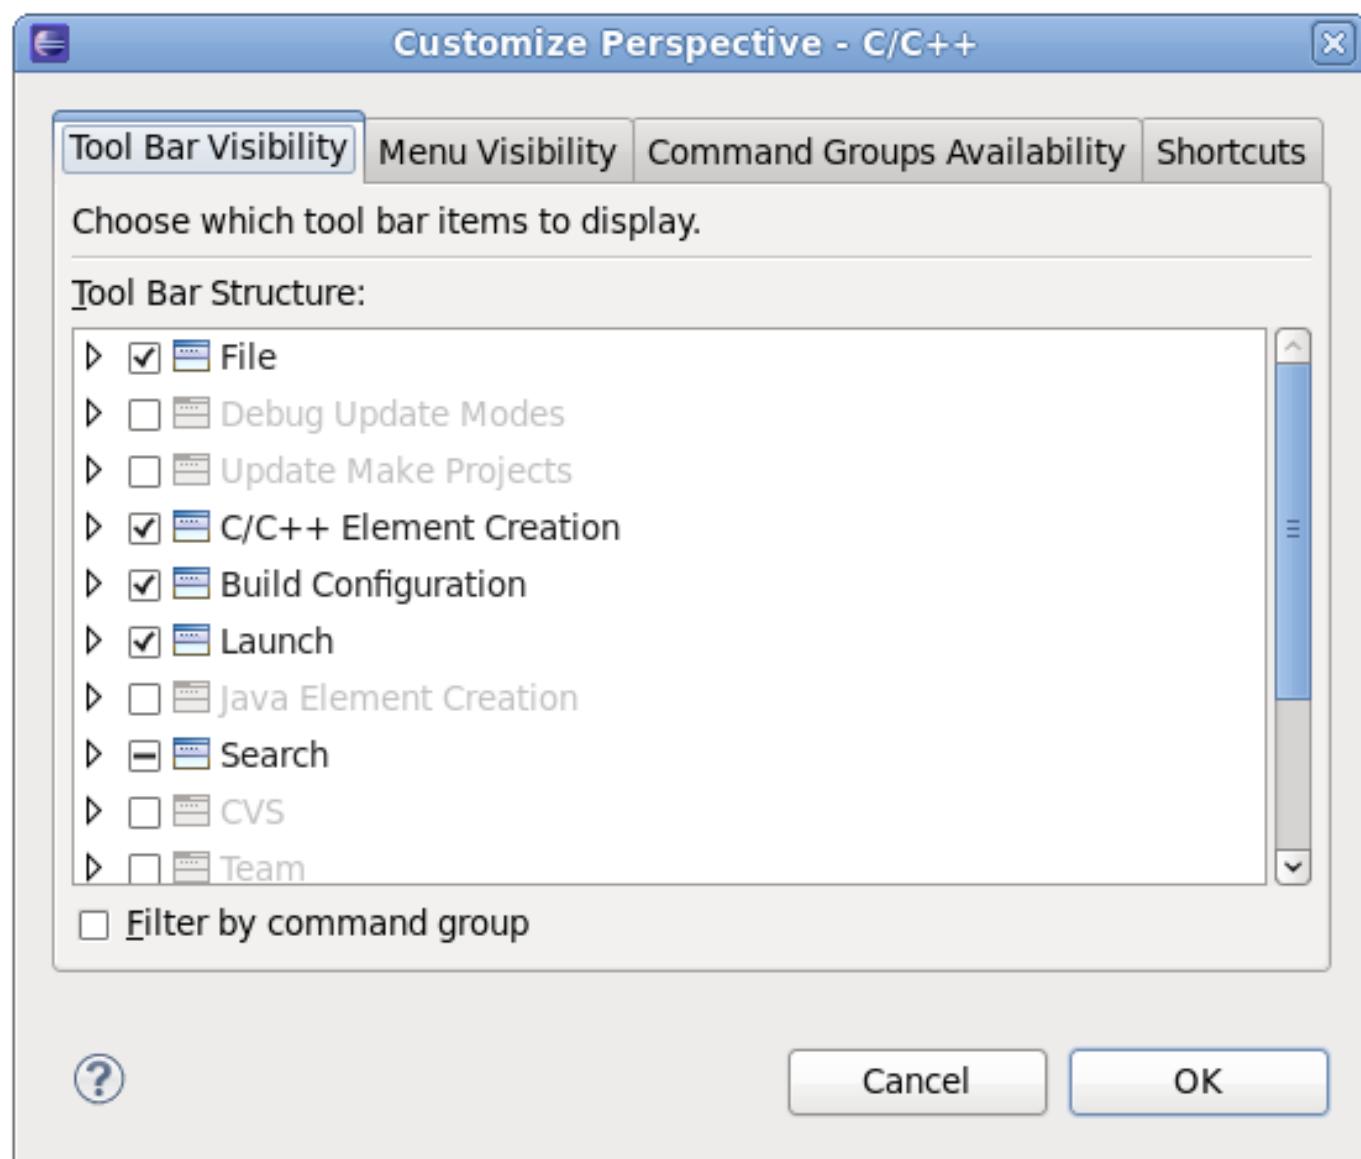

**Figure 1.15. Configuring Keyboard Shortcuts**

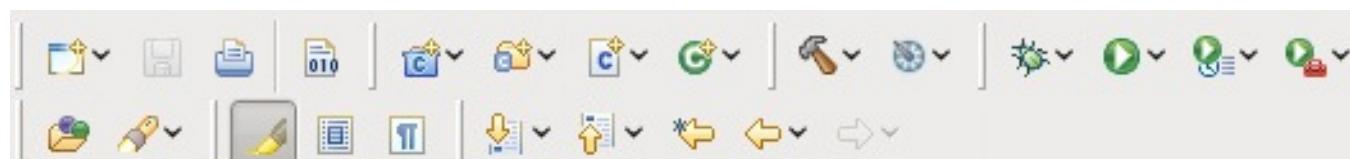

### 1.2.3. Customize Perspective

To customize the current perspective, navigate to **Window > Customize Perspective**. This opens the **Customize Perspective** menu, allowing the visible tool bars, main menu items, command groups, and shortcuts to be configured.

The location of each view within the workbench can be customized by clicking on a view's title and dragging it to a desired location.

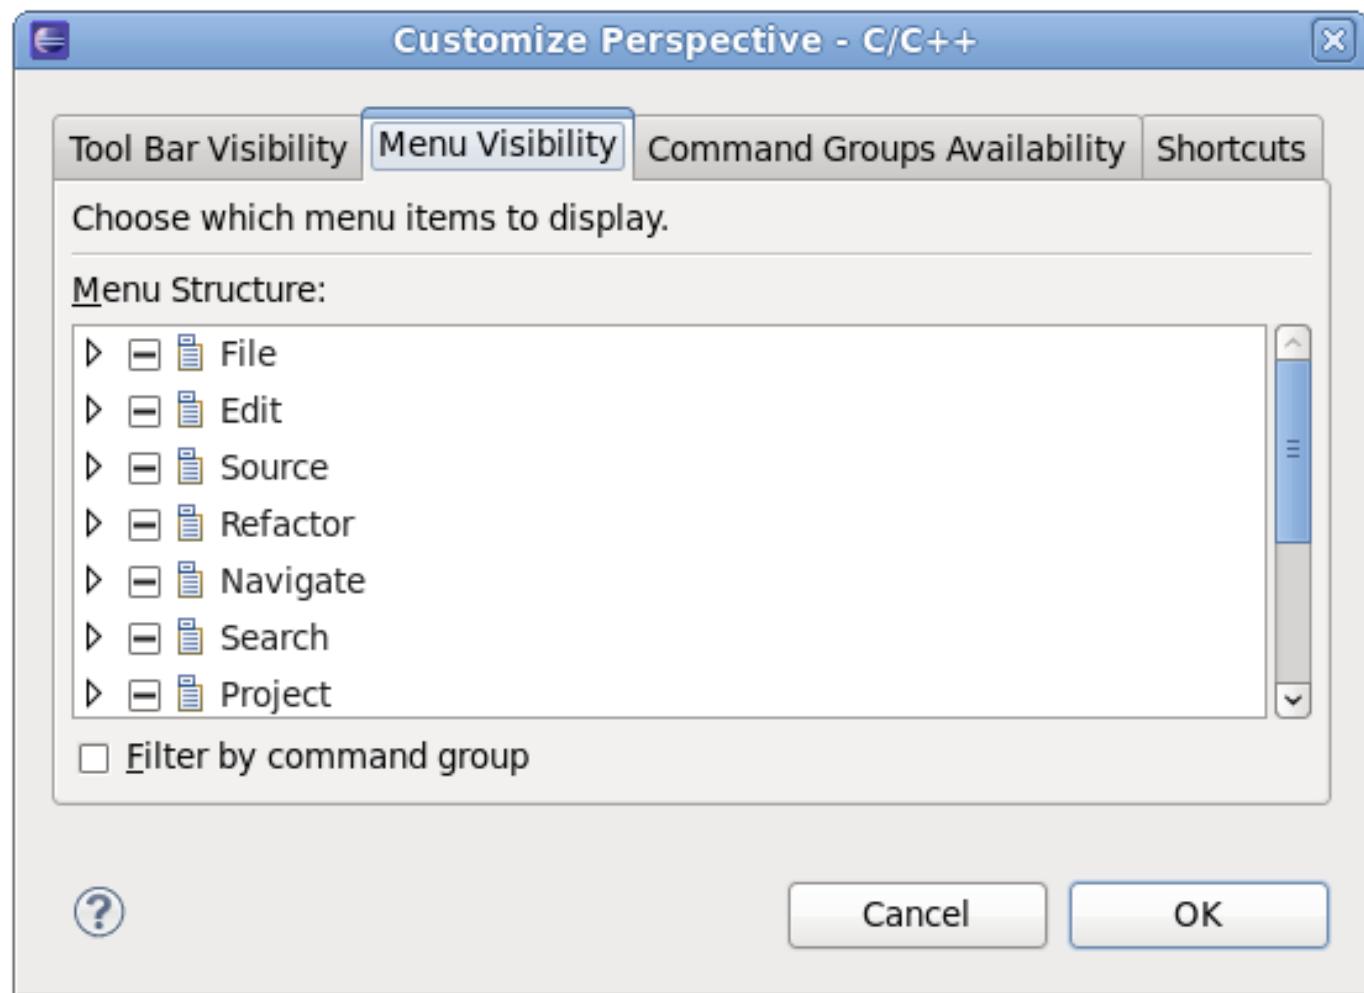

**Figure 1.16. Customize Perspective Menu**

[Figure 1.16, “Customize Perspective Menu”](#) displays the **Tool Bar Visibility** tab. As the name suggests, this tab allows you to toggle the visibility of the tool bars ([Figure 1.17, “Toolbar”](#)).

**Figure 1.17. Toolbar**

The following figures display the other tabs in the **Customize Perspective Menu**:

**Figure 1.18. Menu Visibility Tab**

The **Menu Visibility** tab configures what functions are visible in each main menu item. For a brief overview of each main menu item, see *Reference > C/C++ Menubar* in the *C/C++ Development User Guide* or *Reference > Menus and Actions* in the *Java Development User Guide*.

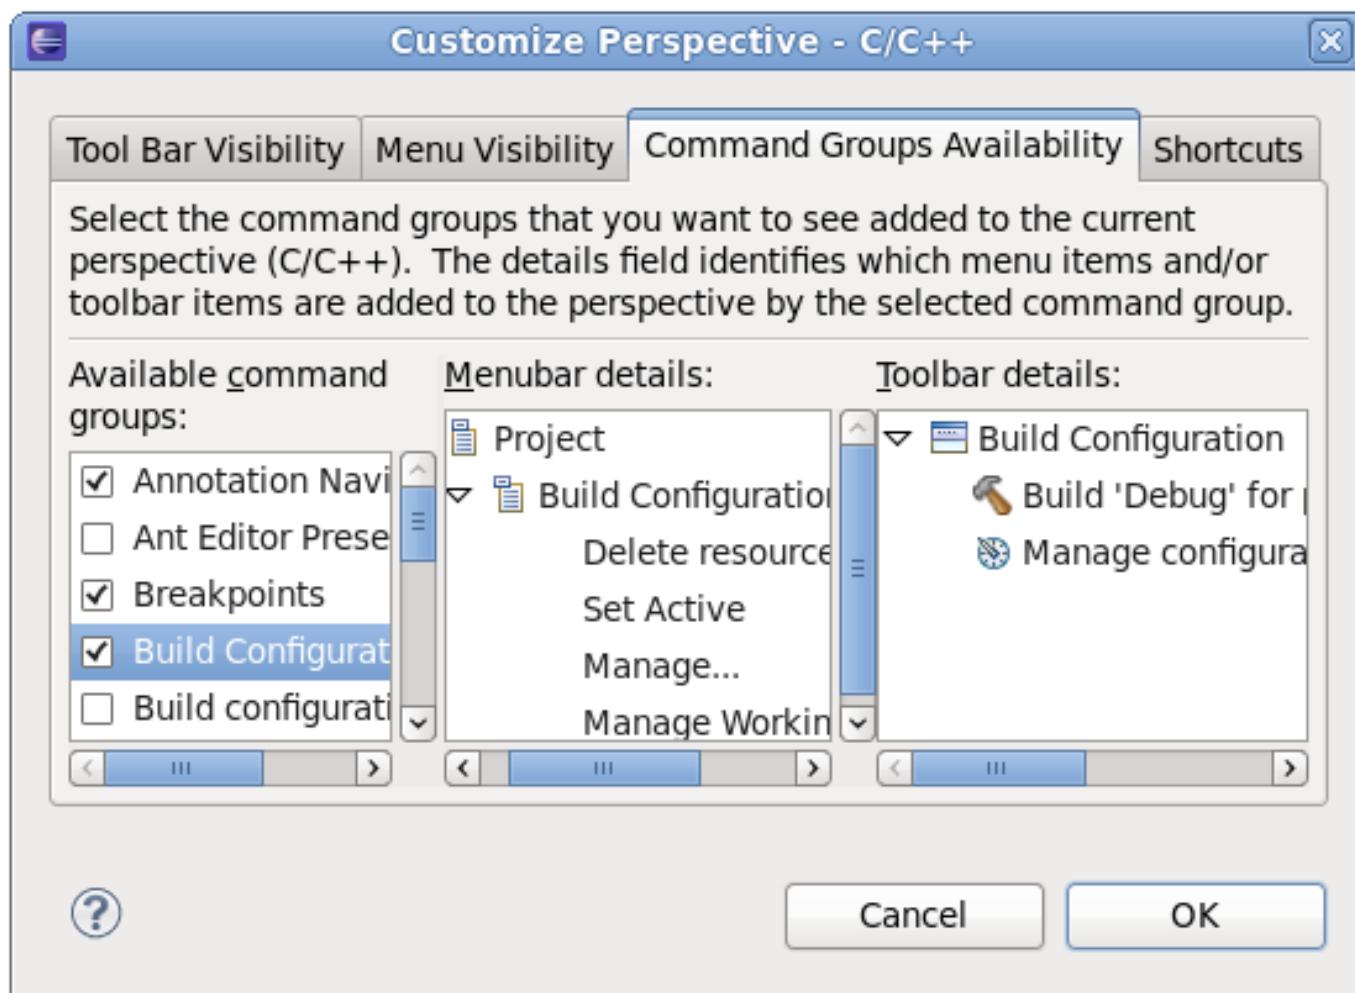

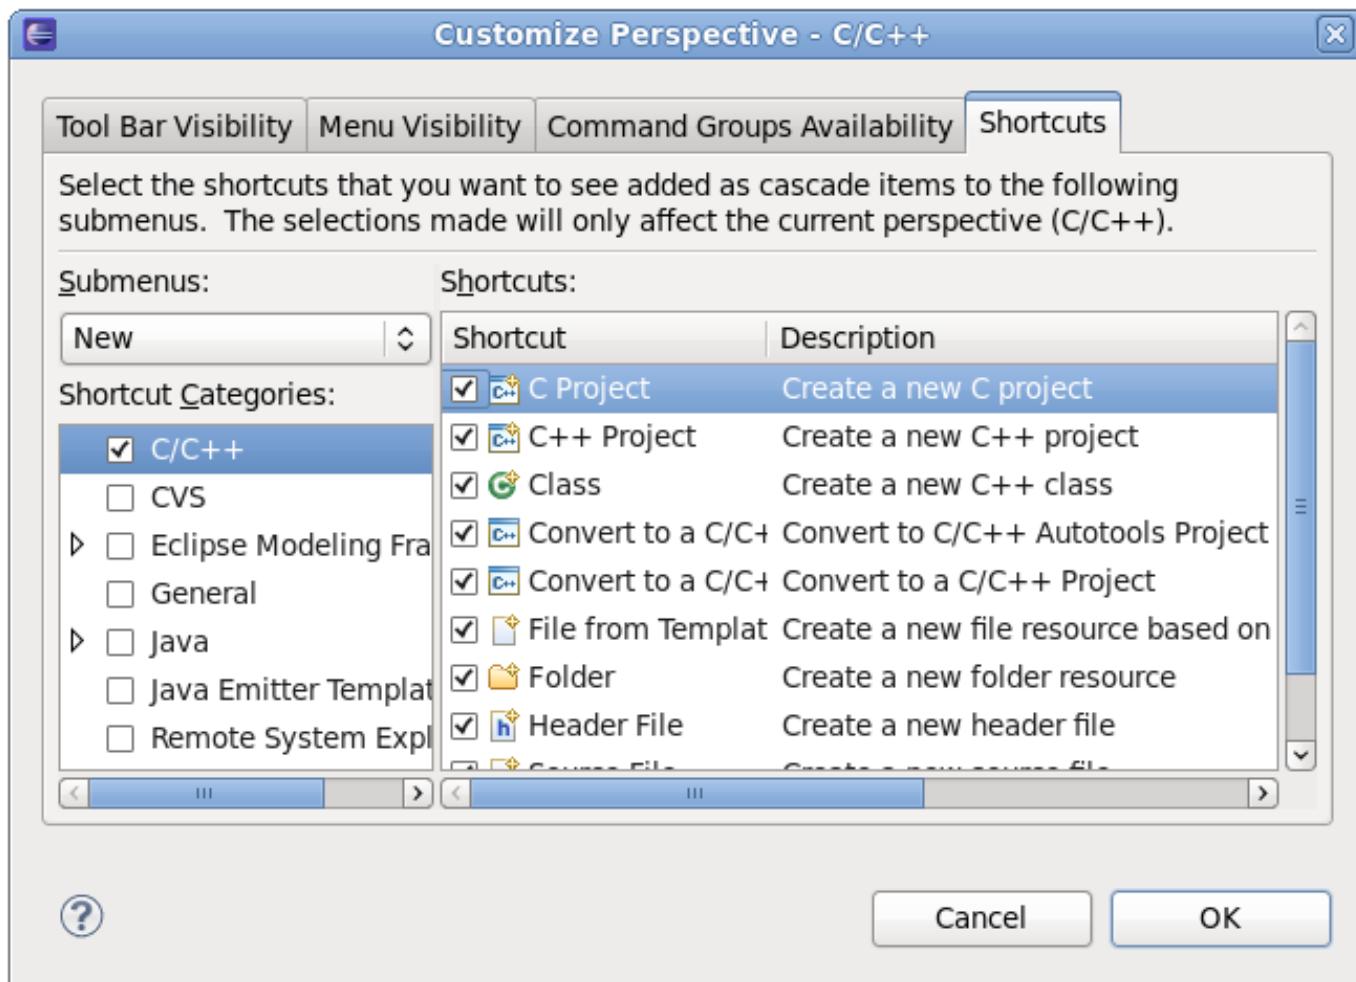

Figure 1.19. Command Group Availability Tab

Command groups add functions or options to the main menu or tool bar area. Use the **Command Group Availability** tab to add or remove a Command group. The **Menubar details** and **Toolbar details** fields display the functions or options added by the Command group to either Main Menu or Toolbar Area, respectively.

**Figure 1.20. Shortcuts Tab**

The **Shortcuts** tab configures what menu items are available under the following submenus:

- » **File > New**
- » **Window > Open Perspective**
- » **Window > Show View**

### 1.3. Editing C/C++ Source Code in Eclipse

Red Hat Enterprise Linux 6 provides Eclipse plug-ins for C/C++ development with the CDT. Specialized editors for C/C++ source code, makefiles, and GNU Autotools files are included. Functionality is also available for running and debugging programs.

The Eclipse text editor supports most of the features expected in a text editor, such as cut, copy, paste, and block selection (**Ctrl+Shift+A**). It also has some relatively unusual features, such as the ability to move a selection (**Alt+Up/Down Arrow**).

Of particular interest to C/C++ programmers is the *Content Assist* feature. This feature presents a pop-up window with possible functions, variables, and templates for the current file/location. It is invoked by pressing **Ctrl+Space** while the cursor is at the desired location.

See [Section 1.3.1, “libhover Plug-in”](#) for more information on completion of function calls from libraries.

The Eclipse C/C++ code editor also has error highlighting and refactoring.

Code errors and warnings are annotated with colored wavy underlines. These errors and warnings may be present as code is entered into the editor, or they may be present only after a build has occurred and the compiler output has been transformed into these markers.

The provided refactoring tools include the ability to rename code elements. This change can then be reflected in both uses and declarations of the function.

See [Section 5.6, “Debugging C/C++ Applications with Eclipse”](#), or [Section 4.3.1, “Autotools Plug-in for Eclipse”](#) for more information, or see **Concepts** → **Coding aids**, **Concepts** → **Editing C/C++ Files**, and **Tasks** → **Write code** in the *C/C++ Development User Guide*, found in the Help Contents.

### 1.3.1. libhover Plug-in

The **libhover** plug-in for Eclipse provides plug-and-play hover help support for the GNU C Library and GNU C++ Standard Library. This allows developers to see existing documentation on **glibc** and **libstdc++** libraries within the Eclipse IDE in a more seamless and convenient manner via *hover help* and *code completion*.

#### C++ Language

Documentation for member-function completion is not supported for C++; only the prototypes from header files are supplied. In addition, the ability to add header files to the source file is not supported for C++ member functions.

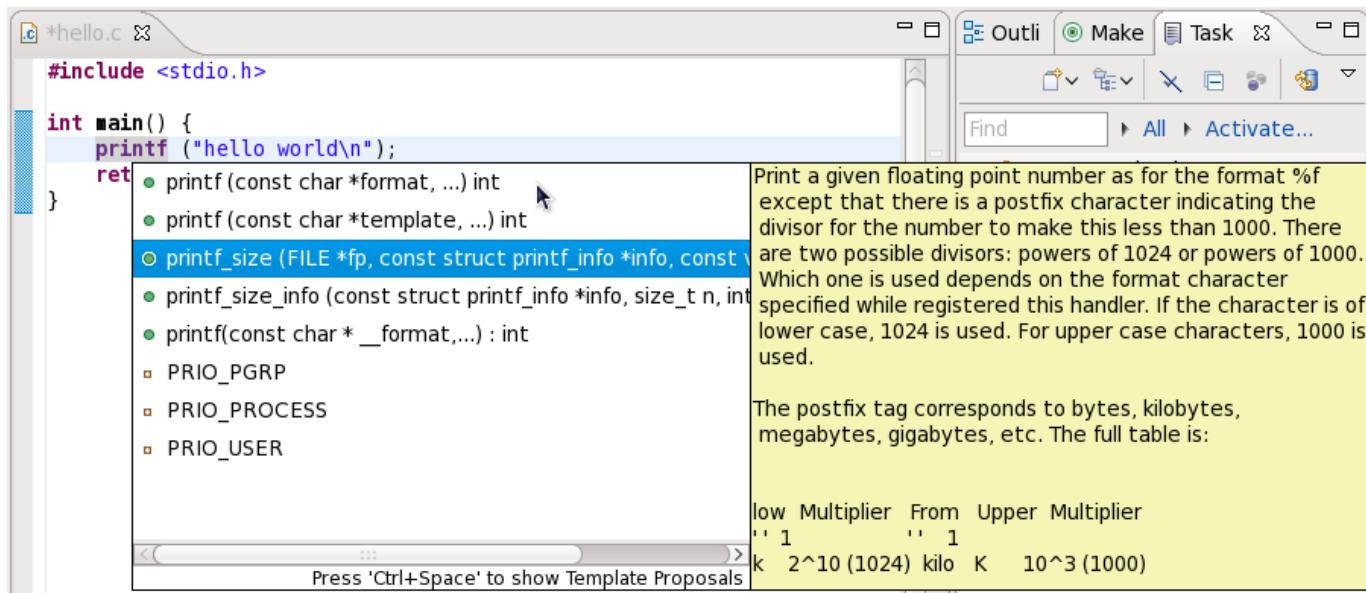

For C++ library resources, **libhover** has to *index* the file using the CDT indexer. Indexing parses the given file in context of a build; the build context determines where header files come from and how types, macros, and similar items are resolved. To be able to index a C++ source file, **libhover** usually requires an actual build to be performed first, although in some cases it may already know where the header files are located.

A C++ member function name is not enough information to look up its documentation so the **libhover** plug-in may require indexing for C++ sources. C++ allows different classes to have members of the same name, and even within a class, members may have the same name but with different member-function signatures. This requires the class name and parameter signature of the function to be provided to determine exactly which member is being referenced.

In addition, C++ also has type definitions and templated classes. Such information requires parsing an entire file and its associated **include** files; **libhover** can only do this via indexing.

#### C Language

For C functions, performing a completion (**Ctrl+Space**) will provide the list of C functions added to the potential sources (for example, typing `prin` and then hitting **Ctrl+Space** will list `printf` as one of the possible completions) and the documentation is viewed in an additional window, for determining exactly what C function is required.

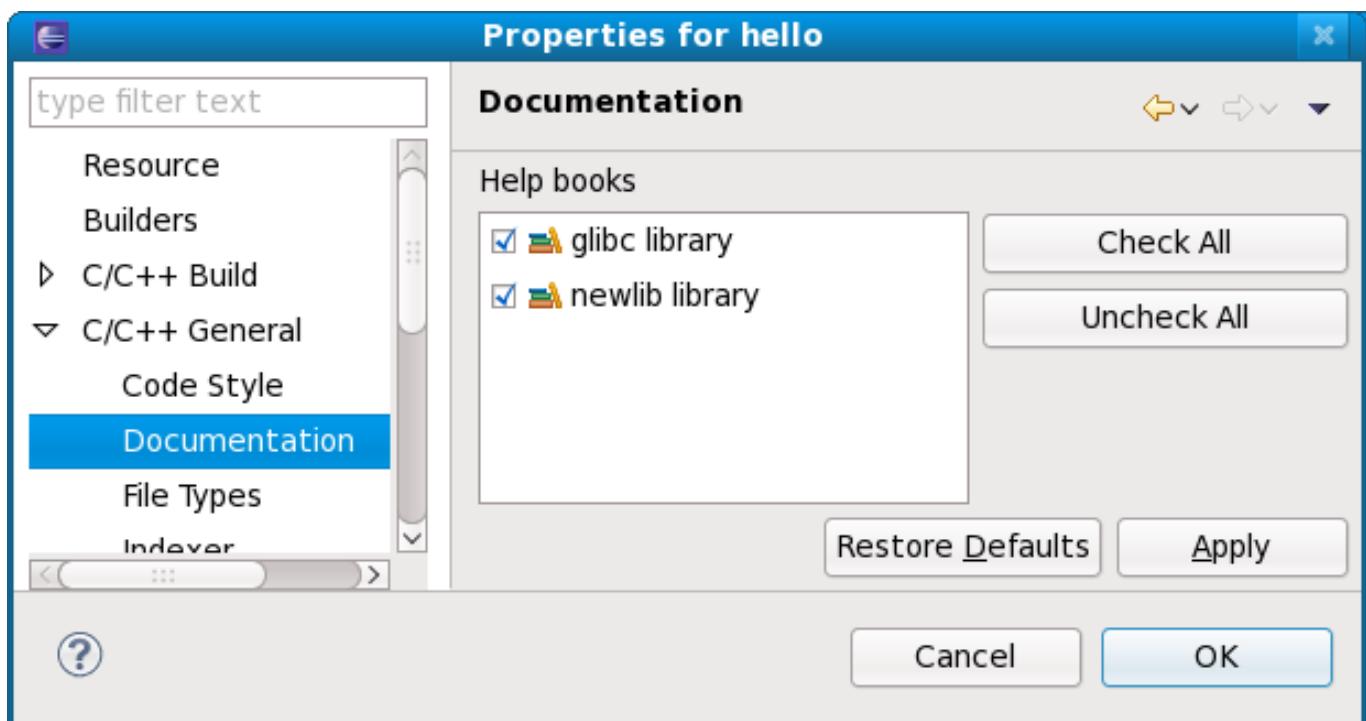

**Figure 1.21. Using Code Completion**

C functions can be referenced in their documentation by name alone. As such, **libhover** does not have to index C source files in order to provide hover help or code completion. The appropriate header file include statement for a C library function can be automatically added if it is not already present.

Select the C function in the file and use right-click > **Source** > **Add Include** to automatically add the required header files to the source. This can also be done using **Shift+Ctrl+N**.

### 1.3.1.1. Setup and Usage

Hover help for all installed **libhover** libraries is enabled by default, and it can be disabled per project. To disable or enable hover help for a particular project, right-click the project name and click **Properties**. On the menu that appears, navigate to **C/C++ General > Documentation**. Check or uncheck a library in the **Help books** section to enable or disable hover help for that particular library.

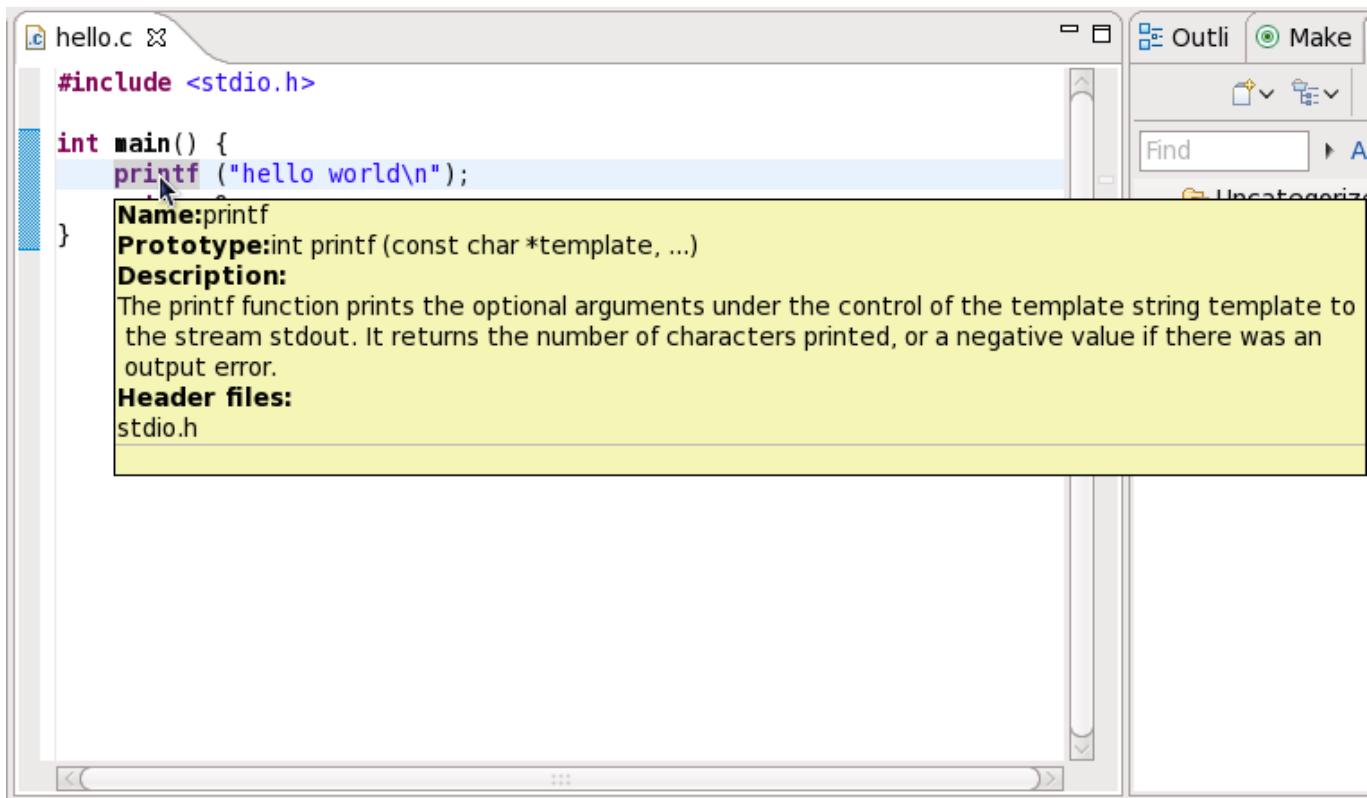

**Figure 1.22. Enabling/Disabling Hover Help**

Disabling hover help from a particular library may be preferable, particularly if multiple **libhover** libraries overlap in functionality. For example, if a **libhover** plug-in for a C library were manually installed, such as the **newlib** C Library (note that **newlib** C library plug-in is not provided in Red Hat Enterprise Linux 6). The hover help would contain C functions whose names overlap with those in the GNU C library (provided by default). A user would not want both of these hover helps active at once, so disabling one would be practical.

When multiple **libhover** libraries are enabled and there exists a functional overlap between libraries, the Help content for the function from the *first* listed library in the **Help books** section will appear in hover help (that is, in [Figure 1.22, “Enabling/Disabling Hover Help”, glibc](#)). For code completion, **libhover** will offer all possible alternatives from all enabled **libhover** libraries.

To use hover help, hover the mouse over a function name or member function name in the **C/C++ Editor**. After a short time, no more than a few seconds, **libhover** will display library documentation on the selected C function or C++ member function.

**Figure 1.23. Using Hover Help**

## 1.4. Editing Java Source Code in Eclipse

Red Hat Enterprise Linux 6 provides Eclipse plug-ins for Java (Java SE) development with the JDT. Specialized editors for Java source code as well as for ant **build.xml** files are included. Functionality is also available for running and debugging programs.

Eclipse provides a fully-featured interactive development environment for Java developers.

### New Project Wizard

Eclipse's **New Project Wizard** performs most of the boilerplate setup required to start a Java project. This allows the user to select and customize various options, such as which Java Runtime Environment to use, or the preferred project file tree layout.

Follow the same procedure to export an existing project, and when prompted for a location, enter the existing project's location instead.

For more information regarding setting up a new Java project, see **Help > Help Contents > Java Development > Getting Started > Basic Tutorial > Creating Your First Java Project**.

### Content Assistance

The Eclipse Java Development Environment (JDT) increases productivity and reduces errors by providing a rich set of content assistance features, usually invoked by pressing **Ctrl + Space**. This includes completion for method names in your code or in libraries, inserting parameter names in Javadoc, and filling in parameters when calling a method. This is fully customizable, allowing the options of suppressing certain suggestions or adding custom code templates to be filled in while writing code.

For an overview of these features, see **Help > Help Contents > Java Development User Guide > Tips and Tricks**.

## Code Formatting

Code formatting, accessed by pressing **Ctrl + Shift + F**, is another useful feature present in the JDT. The formatting settings can be changed by navigating to **Window > Preferences > Java > Code Styler > Formatter** where there is the option of using a set of installed formatting profiles, or creating a new one to fit the style of the project.

## Debugging Features

The JDT also comes with several debugging features. Create breakpoints by double-clicking on the left hand margin at the desired line of code. When the debugger is run, the program will stop at that line of code which is useful in detecting the location of errors.

The Debug Perspective, configured the first time the debugger is run, is a different layout that makes views related to debugging more prominent. For example, the **Expressions** view allows evaluation of Java expressions in the context of the current frame.

The views that make up the Debug Perspective, like all views, are accessed through **Window > Show View** and you do not have to be debugging to access these views.

While debugging, hover over variables to view their values or use the **Variables** view. Using the Debug view, it is possible to control the execution of programs and explore the various frames on the stack.

For more information on debugging in the JDT, see **Help > Help Contents > Java Development > Getting Started > Basic Tutorial > Debugging Your Programs**.

## JDT Features

The JDT is highly customizable and comes with an extensive feature list which can be viewed through the settings in **Window > Preferences > Java**, and through the Java settings in **Project > Properties**. For detailed documentation of the JDT and its features, see the *Java Development User Guide* found in **Help > Help Contents > Java Development User Guide**.

## 1.5. Eclipse RPM Building

The Specfile Editor Plug-in for Eclipse provides useful features to help developers manage **.spec** files. This plug-in allows users to leverage several Eclipse GUI features in editing **.spec** files, such as auto-completion, highlighting, file hyperlinks, and folding.

In addition, the Specfile Editor Plug-in also integrates the **rpmlint** tool into the Eclipse interface. **rpmlint** is a command line tool that helps developers detect common RPM package errors. The richer visualization offered by the Eclipse interface helps developers quickly detect, view, and correct mistakes reported by **rpmlint**.

The Eclipse **.spec** file editor plug-in also supports building RPM files from RPM projects. This feature can be used by employing an export wizard (**Import → RPM → Source/Binary RPM**) allowing the selection of whether a source RPM (**src.rpm**), binary RPM, or both, are required.

Build output is in the Eclipse Console view. For a limited number of build failures, there is hyperlinking support. That is, certain parts of the build failure are changed to be a hyperlink (**Ctrl+Click**) in the Eclipse Console view, which then points the user to the actual line in the **.spec** file that is causing the problem.

Also of note is the wizard for importing source RPM (`.src.rpm`) files, found in **Import → RPM → Source RPM**). This allows the user to easily start with no configuration required, in case a source RPM has already been created. This project is then ready for editing the spec file and building (exporting) to source/binary RPMs.

For further details, see the **Specfile Editor User Guide → Import src.rpm and export rpm and src.rpm** section in the *Specfile Editor User Guide* in Help Contents.

## 1.6. Eclipse Documentation

Eclipse features a comprehensive internal help library that covers nearly every facet of the Integrated Development Environment (IDE). Every Eclipse documentation plug-in installs its content to this library, where it is indexed. To access this library, use the **Help** menu.

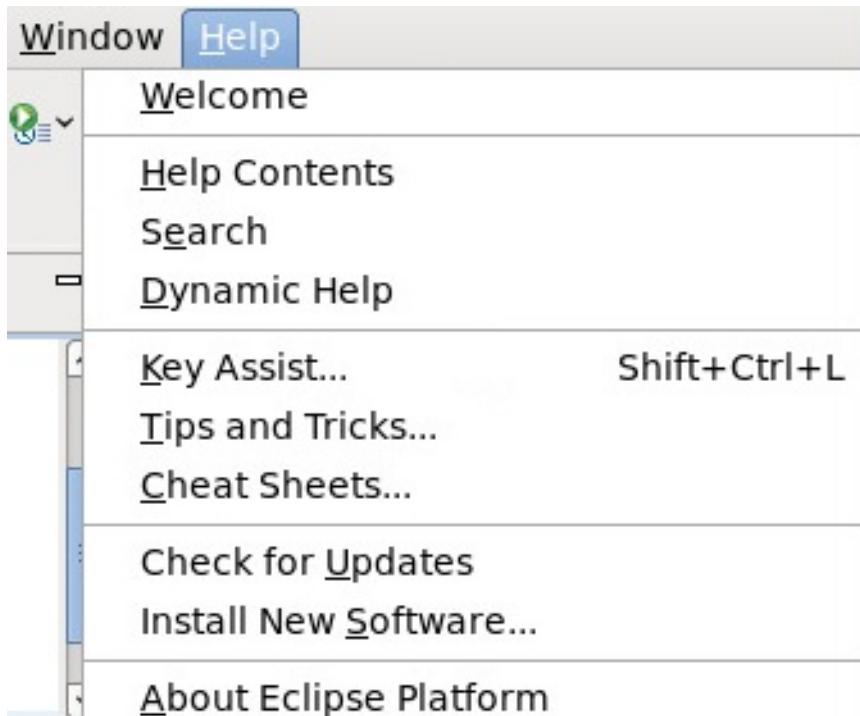

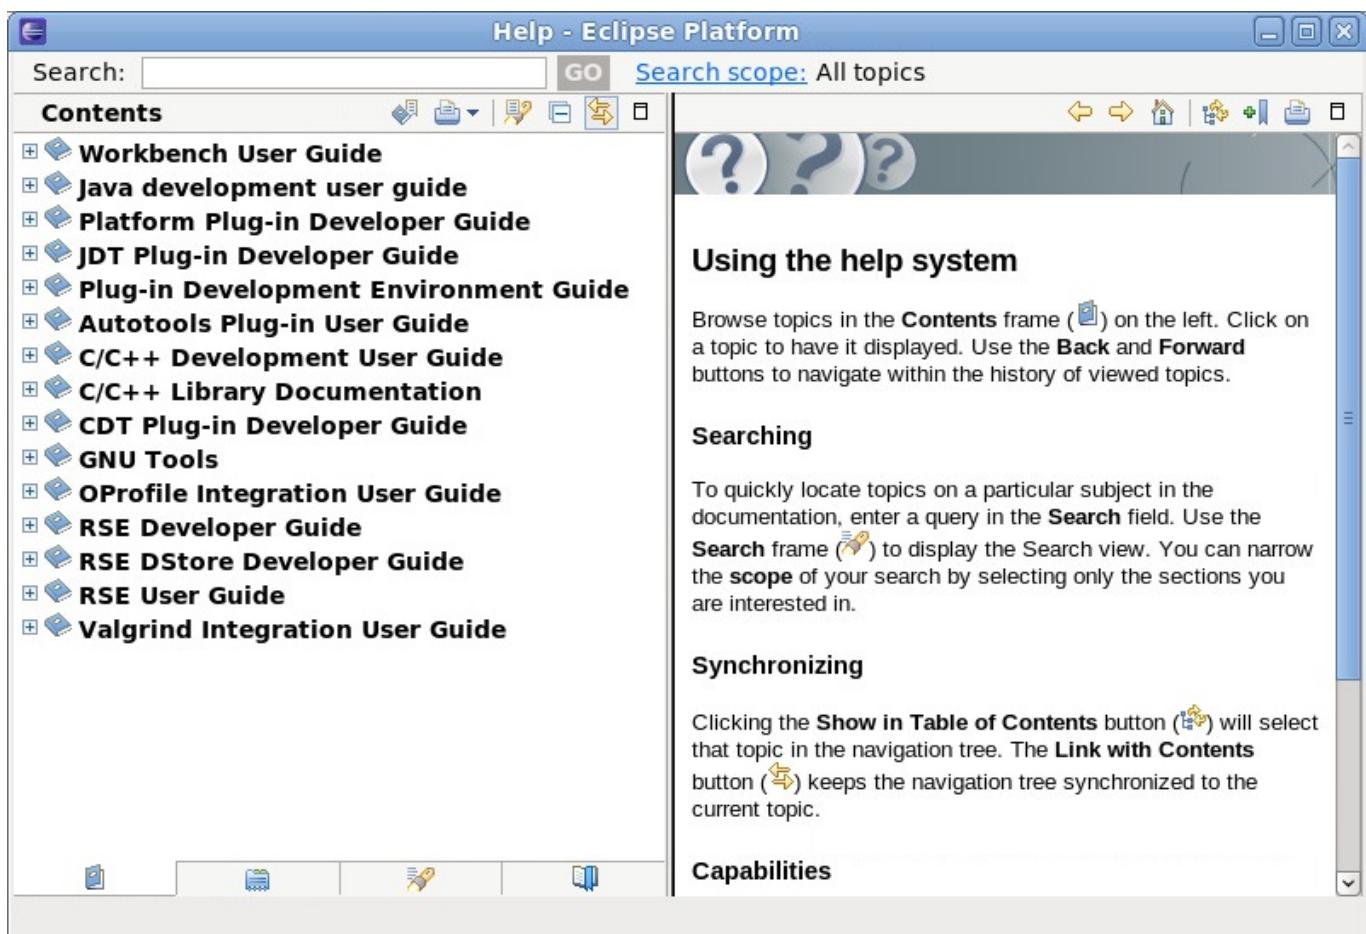

Figure 1.24. Help

To open the main **Help** menu, navigate to **Help > Help Contents**. The **Help** menu displays all the available content provided by installed documentation plug-ins in the **Contents** field.

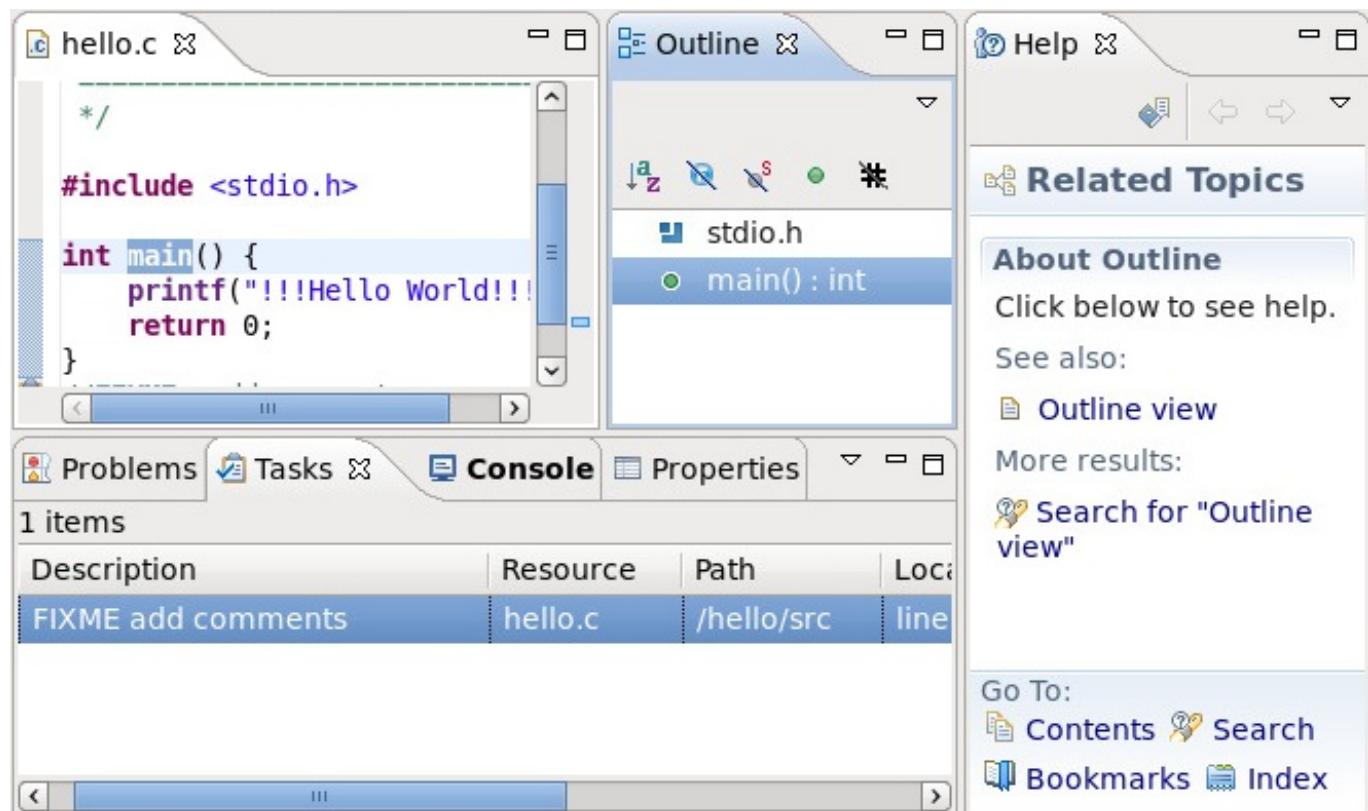

**Figure 1.25. Help Menu**

The tabs at the bottom of the **Contents** field provides different options for accessing Eclipse documentation. You can navigate through each "book" by section/header or by searching via the **Search** field. You can also bookmark sections in each book and access them through the **Bookmarks** tab.

The *Workbench User Guide* documents all facets of the Eclipse user interface extensively. It contains very low-level information on the Eclipse workbench, perspectives, and different concepts useful in understanding how Eclipse works. The *Workbench User Guide* is an ideal resource for users with little to intermediate experience with Eclipse or IDEs in general. This documentation plug-in is installed by default.

The Eclipse help system also includes a *dynamic help* feature. This feature opens a new window in the workbench that displays documentation relating to a selected interface element. To activate dynamic help, navigate to **Help > Dynamic Help**.

**Figure 1.26. Dynamic Help**

The rightmost window in [Figure 1.26, “Dynamic Help”](#) displays help topics related to the **Outline** view, which is the selected user interface element.

## Chapter 2. Collaborating

Effective revision control is essential to all multi-developer projects. It allows all developers in a team to create, review, revise, and document code in a systematic and orderly manner. Red Hat Enterprise Linux 6 supports three of the most popular open source revision control systems: CVS, SVN, and Git. The tools for these revision control systems provide access to a wide range of publicly available open source code, as well as the capability to set up individual internal code repositories.

The following section provides a brief overview and references to relevant documentation for each tool.

### 2.1. Concurrent Versions System (CVS)

**Concurrent Versions System**, commonly abbreviated as **CVS**, is a *centralized version control system* with a client-server architecture. It is a successor to the older Revision Control System (RCS), and allows multiple developers to cooperate on the same project while keeping track of every change made to the files that are under revision control.

#### 2.1.1. Installing and Configuring CVS

##### Installing the cvs Package

In Red Hat Enterprise Linux 6, **CVS** is provided by the **cvs** package. To install the **cvs** package and all its dependencies on your system, type the following at a shell prompt as **root**:

```
yum install cvs
```

This installs a command line CVS client, a CVS server, and other related tools to the system.

##### Setting Up the Default Editor

When using CVS on the command line, certain commands such as **cvs import** or **cvs commit** require the user to write a short log message. To determine which text editor to start, the **cvs** client application first reads the contents of the environment variable **\$CVSEDITOR**, then reads the more general environment variable **\$EDITOR**, and if none of these is set, it starts **vi**.

To persistently change the value of the **\$CVSEDITOR** environment variable, run the following command:

```
echo "export CVSEDITOR=command" >> ~/.bashrc
```

This adds the **export CVSEDITOR=command** line to your **~/.bashrc** file. Replace **command** with a command that runs the editor of your choice (for example, **emacs**). Note that for this change to take effect in the current shell session, you must execute the commands in **~/.bashrc** by typing the following at a shell prompt:

```
. ~/.bashrc
```

##### Example 2.1. Setting up the default text editor

To configure the CVS client to use **Emacs** as a text editor, type:

```
~]$ echo "export CVSEDITOR=emacs" >> ~/.bashrc
~]$ . ~/.bashrc
```

## 2.1.2. Creating a New Repository

A CVS *repository* is a central place to store files and directories that are under revision control, as well as additional data such as a complete history of changes or information about who made those changes and when. A typical CVS repository stores multiple projects in separate subdirectories called *modules*. When publicly accessible, it allows several developers to create a *working copy* of any of the modules, make changes, and share these changes with others by *committing* them back to the repository.

### Initializing an Empty Repository

To create a new, empty CVS repository in a directory of your choice, run the following command:

```
cvs -d path init
```

Note that *path* must be an absolute path to the directory in which you want to store the repository (for example, `/var/cvs/`). Alternatively, you can specify this path by changing the value of the `$CVSROOT` environment variable:

```
export CVSROOT=path
```

This allows you to omit the path from `cvs init` and other CVS-related commands:

```
cvs init
```

### Example 2.2. Initializing a new CVS repository

To create an empty CVS repository in the `~/cvs/` directory, type:

```
~]$ export CVSROOT=~/cvs
~]$ cvs init
```

### Importing Data to a Repository

To put an existing project under revision control, change to the directory in which the project is stored and run the following command:

```
cvs [-d cvs_repository] import [-m "commit message"] module vendor_tag
release_tag
```

Note that `cvs_repository` is a path to the CVS repository, `module` is the subdirectory in which you want to import the project (such as `project`), and `vendor_tag` and `release_tag` are vendor and release tags.

### Example 2.3. Importing a project to a CVS repository

Imagine that the directory with your project has the following contents:

```
~]$ ls myproject
AUTHORS doc INSTALL LICENSE Makefile README src TODO
```

Also imagine that you have an empty CVS repository in `~/cvs/`. To import the project under `project` in this repository with vendor tag `mycompany` and release tag `init`, type:

```
myproject]$ export CVSROOT=~/cvs
myproject]$ cvs import -m "Initial import." project mycompany init
N project/Makefile
N project/AUTHORS
N project/LICENSE
N project/TODO
N project/INSTALL
...
...
```

### 2.1.3. Checking Out a Working Copy

To check out a working copy of a project in a CVS repository, run the following command:

```
cvs -d cvs_repository checkout module
```

This creates a new directory called `module` with a working copy of a project in it. Note that `cvs_repository` is a URL of the CVS repository and `module` is the subdirectory in which the project is stored (such as `project`). Alternatively, you can set the `$CVSROOT` environment variable as follows:

```
export CVSROOT=cvs_repository
```

Then you can use the `cvs checkout` command without the `-d` option:

```
cvs checkout module
```

#### Example 2.4. Checking out a working copy

Imagine that you have a CVS repository in `~/cvs/` and that this repository contains a module named `project`. To check out a working copy of this module, type:

```
~]$ export CVSROOT=~/cvs
~]$ cvs checkout project
cvs checkout: Updating project
U project/AUTHORS
U project/INSTALL
U project/LICENSE
U project/Makefile
U project/TODO
```

### 2.1.4. Adding and Deleting Files

#### Adding a File

To add an existing file to a CVS repository and put it under revision control, change to the directory with its working copy and run the following command:

```
cvs add file...
```

This schedules the file for addition to the CVS repository. To proceed and actually add the file to the repository, run the **cvs commit** command as described in [Section 2.1.6, “Committing Changes”](#).

### Example 2.5. Adding a file to a CVS repository

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  CVS  doc  INSTALL  LICENSE  Makefile  README  src
TODO
```

With the exception of **ChangeLog**, all files and directories within this directory are already under revision control. To schedule this file for addition to the CVS repository, type:

```
project]$ cvs add ChangeLog
cvs add: scheduling file `ChangeLog' for addition
cvs add: use 'cvs commit' to add this file permanently
```

## Deleting a File

To remove a file from a CVS repository, change to the directory with its working copy and delete it locally:

```
rm file...
```

Then schedule this file for removal by using the following command:

```
cvs remove file...
```

To proceed and actually remove the file from the repository, run the **cvs commit** command as described in [Section 2.1.6, “Committing Changes”](#).

### Example 2.6. Removing a file from a CVS repository

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  CVS  doc  INSTALL  LICENSE  Makefile  README  src
TODO
```

All files in this directory are under revision control. To schedule the **TODO** file for removal from the CVS repository, type:

```
project]$ rm TODO
project]$ cvs remove TODO
cvs remove: scheduling `TODO' for removal
cvs remove: use 'cvs commit' to remove this file permanently
```

## 2.1.5. Viewing Changes

### Viewing the Status

To determine the current status of a working copy, change to the directory with the working copy and run the following command:

```
cvs status
```

This displays detailed information about each file that is under revision control, including its current status (such as **Up-to-date**, **Locally Added**, **Locally Removed**, or **Locally Modified**) and revision. However, if you are only interested in what has changed in your working copy, you can simplify the output by typing the following at a shell prompt:

```
cvs status 2>/dev/null | grep Status: | grep -v Up-to-date
```

### Example 2.7. Viewing the status of a working copy

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  CVS  doc  INSTALL  LICENSE  Makefile  README  src
```

With the exception of **ChangeLog**, which is scheduled for addition to the CVS repository, all files and directories within this directory are already under revision control. The **TODO** file, which is also under revision control, has been scheduled for removal and is no longer present in the working copy. Finally, **Makefile** contains local changes. To display the status of such a working copy, type:

```
project]$ cvs status 2>/dev/null | grep Status: | grep -v Up-to-date
File: ChangeLog           Status: Locally Added
File: Makefile             Status: Locally Modified
File: no file TODO         Status: Locally Removed
```

### Viewing Differences

To view differences between a working copy and the checked out content, change to the directory with the working copy and run the following command:

```
cvs diff [file...]
```

This displays changes to all files in the working copy. If you are only interested in changes to a particular file, supply the file name on the command line.

**Example 2.8. Viewing changes to a working copy**

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS ChangeLog CVS doc INSTALL LICENSE Makefile README src
```

All files in this directory are under revision control and **Makefile** contains local changes. To view these changes, type:

```
project]$ cvs diff
cvs diff: Differing .
cvs diff: ChangeLog is a new entry, no comparison available
Index: Makefile
=====
RCS file: /home/john/cvs/project/Makefile,v
retrieving revision 1.1.1.1
diff -r1.1.1.1 Makefile
156c156
<      -rm -f $(MAN1)
---
>      -rm -f $(MAN1) $(MAN7)
cvs diff: TODO was removed, no comparison available
cvs diff: Differing doc
...
```

**2.1.6. Committing Changes**

To share your changes with others and commit them to a CVS repository, change to the directory with its working copy and run the following command:

```
cvs commit [-m "commit message"]
```

Note that unless you specify the commit message on the command line, CVS opens an external text editor (**vi** by default) for you to write it. For information on how to determine which editor to start, see [Section 2.1.1, “Installing and Configuring CVS”](#).

**Example 2.9. Committing changes to a CVS repository**

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS ChangeLog CVS doc INSTALL LICENSE Makefile README src
```

In this working copy, **ChangeLog** is scheduled for addition to the CVS repository, **Makefile** already is under revision control and contains local changes, and the **TODO** file, which is also under revision control, has been scheduled for removal and is no longer present in the working copy. To commit these changes to the CVS repository, type:

```
project]$ cvs commit -m "Updated the makefile."
cvs commit: Examining .
cvs commit: Examining doc
```

```

...
RCS file: /home/john/cvsroot/project/ChangeLog,v
done
Checking in ChangeLog;
/home/john/cvsroot/project/ChangeLog,v  <--  ChangeLog
initial revision: 1.1
done
Checking in Makefile;
/home/john/cvsroot/project/Makefile,v  <--  Makefile
new revision: 1.2; previous revision: 1.1
done
Removing TODO;
/home/john/cvsroot/project/TODO,v  <--  TODO
new revision: delete; previous revision: 1.1.1.1
done

```

## 2.1.7. Updating a Working Copy

To update a working copy and get the latest changes from a CVS repository, change to the directory with the working copy and run the following command:

**cvs update**

### Example 2.10. Updating a working copy

Imagine that the directory with your working copy of a CVS repository has the following contents:

```
project]$ ls
AUTHORS  CVS  doc  INSTALL  LICENSE  Makefile  README  src  TODO
```

Also imagine that somebody recently added **ChangeLog** to the repository, removed the **TODO** file from it, and made some changes to **Makefile**. To update this working copy, type:

```
myproject]$ cvs update
cvs update: Updating .
U ChangeLog
U Makefile
cvs update: TODO is no longer in the repository
cvs update: Updating doc
cvs update: Updating src
```

## 2.1.8. Additional Resources

A detailed description of all supported features is beyond the scope of this book. For more information, see the resources listed below.

### Installed Documentation

- » **cvs(1)** — The manual page for the **cvs** client program provides detailed information on its usage.

## 2.2. Apache Subversion (SVN)

**Apache Subversion**, commonly abbreviated as **SVN**, is a *centralized version control system* with a client-server architecture. It is a successor to the older Concurrent Versions System (CVS), preserves the same development model, and addresses problems often encountered with CVS.

### 2.2.1. Installing and Configuring Subversion

#### Installing the subversion Package

In Red Hat Enterprise Linux 6, **Subversion** is provided by the *subversion* package. To install the *subversion* package and all its dependencies on your system, type the following at a shell prompt as **root**:

```
yum install subversion
```

This installs a command line Subversion client, a Subversion server, and other related tools to the system.

#### Setting Up the Default Editor

When using Subversion on the command line, certain commands such as **svn import** or **svn commit** require the user to write a short log message. To determine which text editor to start, the **svn** client application first reads the contents of the environment variable **\$SVN\_EDITOR**, then reads more general environment variables **\$VISUAL** and **\$EDITOR**, and if none of these is set, it reports an error.

To persistently change the value of the **\$SVN\_EDITOR** environment variable, run the following command:

```
echo "export SVN_EDITOR=command" >> ~/.bashrc
```

This adds the **export SVN\_EDITOR=command** line to your **~/.bashrc** file. Replace **command** with a command that runs the editor of your choice (for example, **emacs**). Note that for this change to take effect in the current shell session, you must execute the commands in **~/.bashrc** by typing the following at a shell prompt:

```
. ~/.bashrc
```

#### Example 2.11. Setting up the default text editor

To configure the Subversion client to use **Emacs** as a text editor, type:

```
~]$ echo "export SVN_EDITOR=emacs" >> ~/.bashrc  
~]$ . ~/.bashrc
```

### 2.2.2. Creating a New Repository

A Subversion *repository* is a central place to store files and directories that are under revision control, as well as additional data such as a complete history of changes or information about who made

those changes and when. A typical Subversion repository stores multiple projects in separate subdirectories. When publicly accessible, it allows several developers to create a *working copy* of any of the subdirectories, make changes, and share these changes with others by *committing* them back to the repository.

## Initializing an Empty Repository

To create a new, empty Subversion repository in a directory of your choice, run the following command:

```
svnadmin create path
```

Note that *path* is an absolute or relative path to the directory in which you want to store the repository (for example, `/var/svn/`). If the directory does not exist, **svnadmin create** creates it for you.

### Example 2.12. Initializing a new Subversion repository

To create an empty Subversion repository in the `~/svn/` directory, type:

```
~]$ svnadmin create svn
```

## Importing Data to a Repository

To put an existing project under revision control, run the following command:

```
svn import local_path svn_repository/remote_path [-m "commit message"]
```

Note that *local\_path* is an absolute or relative path to the directory in which you keep the project (use `.` for the current working directory), *svn\_repository* is a URL of the Subversion repository, and *remote\_path* is the target directory in the Subversion repository (for example, `project/trunk`).

### Example 2.13. Importing a project to a Subversion repository

Imagine that the directory with your project has the following contents:

```
~]$ ls myproject
AUTHORS doc INSTALL LICENSE Makefile README src TODO
```

Also imagine that you have an empty Subversion repository in `~/svn/` (in this example, `/home/john/svn/`). To import the project under `project/trunk` in this repository, type:

```
~]$ svn import myproject file:///home/john/svn/project/trunk -m "Initial import."
Adding project/AUTHORS
Adding project/doc
Adding project/doc/index.html
Adding project/INSTALL
Adding project/src
...
```

### 2.2.3. Checking Out a Working Copy

To check out a working copy of a project in a Subversion repository, run the following command:

```
svn checkout svn_repository/remote_path [directory]
```

This creates a new directory called *directory* with a working copy of a project in it. Note that *svn\_repository* is a URL of the Subversion repository and *remote\_path* is the subdirectory in which the project is stored.

#### Example 2.14. Checking out a working copy

Imagine that you have a Subversion repository in the `~/svn/` directory (in this case, `/home/john/svn/`) and that this repository contains the latest version of a project in the `project/trunk` subdirectory. To check out a working copy of this project, type:

```
~]$ svn checkout svn:///home/john/svn/project/trunk project
A   project/AUTHORS
A   project/doc
A   project/doc/index.html
A   project/INSTALL
A   project/src
...
...
```

### 2.2.4. Adding, Renaming, and Deleting Files

#### Adding a File or Directory

To add an existing file to a Subversion repository and put it under revision control, change to the directory with its working copy and run the following command:

```
svn add file...
```

Similarly, to add a directory and all files that are in it, type:

```
svn add directory...
```

This schedules the files and directories for addition to the Subversion repository. To proceed and actually add this content to the repository, run the **svn commit** command as described in [Section 2.2.6, “Committing Changes”](#).

#### Example 2.15. Adding a file to a Subversion repository

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  doc  INSTALL  LICENSE  Makefile  README  src  TODO
```

With the exception of **ChangeLog**, all files and directories within this directory are already under revision control. To schedule this file for addition to the Subversion repository, type:

```
project]$ svn add ChangeLog
A           ChangeLog
```

## Renaming a File or Directory

To rename an existing file or directory in a Subversion repository, change to the directory with its working copy and run the following command:

```
svn move old_name new_name
```

This creates a duplicate of the original file or directory, schedules it for addition, and automatically deletes the original. To proceed and actually rename the content in the Subversion repository, run the `svn commit` command as described in [Section 2.2.6, “Committing Changes”](#).

### Example 2.16. Renaming a file in a Subversion repository

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  doc  INSTALL  LICENSE  Makefile  README  src  TODO
```

All files in this directory are under revision control. To schedule the **LICENSE** file for renaming to **COPYING**, type:

```
project]$ svn move LICENSE COPYING
A           COPYING
D           LICENSE
```

Note that `svn move` automatically renames the file in your working copy:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  doc  INSTALL  Makefile  README  src  TODO
```

## Deleting a File or Directory

To remove a file from a Subversion repository, change to the directory with its working copy and run the following command:

```
svn delete file...
```

Similarly, to remove a directory and all files that are in it, type:

```
svn delete directory...
```

This schedules the files and directories for removal from the Subversion repository. To proceed and actually remove this content from the repository, run the `svn commit` command as described in [Section 2.2.6, “Committing Changes”](#).

### Example 2.17. Deleting a file from a Subversion repository

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  doc  INSTALL  Makefile  README  src  TODO
```

All files in this directory are under revision control. To schedule the **TODO** file for removal from the SVN repository, type:

```
project]$ svn delete TODO
D          TODO
```

Note that **svn delete** automatically deletes the file from your working copy:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  doc  INSTALL  Makefile  README  src
```

## 2.2.5. Viewing Changes

### Viewing the Status

To determine the current status of a working copy, change to the directory with the working copy and run the following command:

```
svn status
```

This displays information about all changes to the working copy (**A** for a file that is scheduled for addition, **D** for a file that is scheduled for removal, **M** for a file that contains local changes, **C** for a file with unresolved conflicts, **?** for a file that is not under revision control).

### Example 2.18. Viewing the status of a working copy

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  doc  INSTALL  Makefile  README  src
```

With the exception of **ChangeLog**, which is scheduled for addition to the Subversion repository, all files and directories within this directory are already under revision control. The **TODO** file, which is also under revision control, has been scheduled for removal and is no longer present in the working copy. The **LICENSE** file has been renamed to **COPYING**, and **Makefile** contains local changes. To display the status of such a working copy, type:

```
project]$ svn status
D          LICENSE
D          TODO
A          ChangeLog
```

A	+	COPYING
M		Makefile

## Viewing Differences

To view differences between a working copy and the checked out content, change to the directory with the working copy and run the following command:

```
svn diff [file...]
```

This displays changes to all files in the working copy. If you are only interested in changes to a particular file, supply the file name on the command line.

### Example 2.19. Viewing changes to a working copy

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  CVS  doc  INSTALL  Makefile  README  src
```

All files in this directory are under revision control and **Makefile** contains local changes. To view these changes, type:

```
project]$ svn diff Makefile
Index: Makefile
=====
--- Makefile      (revision 1)
+++ Makefile      (working copy)
@@ -153,7 +153,7 @@
 -rmdir $(man1dir)

clean:
-        -rm -f $(MAN1)
+        -rm -f $(MAN1) $(MAN7)

%.1: %.pl
    $(POD2MAN) --section=1 --release="Version $(VERSION)" \
```

## 2.2.6. Committing Changes

To share your changes with others and commit them to a Subversion repository, change to the directory with its working copy and run the following command:

```
svn commit [-m "commit message"]
```

Note that unless you specify the commit message on the command line, Subversion opens an external text editor for you to write it. For information on how to determine which editor to start, see [Section 2.2.1, “Installing and Configuring Subversion”](#).

### Example 2.20. Committing changes to a Subversion repository

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  ChangeLog  COPYING  doc  INSTALL  Makefile  README  src
```

In this working copy, **ChangeLog** is scheduled for addition to the Subversion repository, **Makefile** already is under revision control and contains local changes, and the **TODO** file, which is also under revision control, has been scheduled for removal and is no longer present in the working copy. Additionally, the **LICENSE** file has been renamed to **COPYING**. To commit these changes to the Subversion repository, type:

```
project]$ svn commit -m "Updated the makefile."
Adding          COPYING
Adding          ChangeLog
Deleting        LICENSE
Sending         Makefile
Deleting        TODO
Transmitting   file data ..
Committed revision 2.
```

### 2.2.7. Updating a Working Copy

To update a working copy and get the latest changes from a Subversion repository, change to the directory with the working copy and run the following command:

```
svn update
```

### Example 2.21. Updating a working copy

Imagine that the directory with your working copy of a Subversion repository has the following contents:

```
project]$ ls
AUTHORS  doc  INSTALL  LICENSE  Makefile  README  src  TODO
```

Also imagine that somebody recently added **ChangeLog** to the repository, removed the **TODO** file from it, changed the name of **LICENSE** to **COPYING**, and made some changes to **Makefile**. To update this working copy, type:

```
myproject]$ svn update
D    LICENSE
D    TODO
A    COPYING
A    Changelog
M    Makefile
Updated to revision 2.
```

## 2.2.8. Additional Resources

A detailed description of all supported features is beyond the scope of this book. For more information, see the resources listed below.

### Installed Documentation

- » **svn help** — The output of the **svn help** command provides detailed information on the **svn** usage.
- » **svnadmin help** — The output of the **svnadmin help** command provides detailed information on the **svnadmin** usage.

### Online Documentation

- » [Version Control with Subversion](#) — The official Subversion website refers to the *Version Control with Subversion* manual, which provides an in-depth description of Subversion, its administration and its usage.

## 2.3. Git

**Git** is a *distributed revision control system* with a peer-to-peer architecture. As opposed to centralized version control systems with a client-server model, **Git** ensures that each working copy of a **Git** repository is its exact copy with complete revision history. This not only allows you to work on and contribute to projects without the need to have permission to push your changes to their official repositories, but also makes it possible for you to work with no network connection.

### 2.3.1. Installing and Configuring Git

#### Installing the git Package

In Red Hat Enterprise Linux 6, **Git** is provided by the *git* package. To install the *git* package and all its dependencies on your system, type the following at a shell prompt as **root**:

```
~]# yum install git
```

#### Configuring the Default Text Editor

Certain **Git** commands, such as **git commit**, require the user to write a short message or make some changes in an external text editor. To determine which text editor to start, **Git** attempts to read the value of the **GIT\_EDITOR** environment variable, the **core.editor** configuration option, the **VISUAL** environment variable, and finally the **EDITOR** environment variable in this particular order. If none of these options and variables are specified, the **git** command starts **vi** as a reasonable default option.

To change the value of the **core.editor** configuration option in order to specify a different text editor, type the following at a shell prompt:

```
git config --global core.editor command
```

Replace *command* with the command to be used to start the selected text editor.

### Example 2.22. Configuring the Default Text Editor

To configure **Git** to use **vim** as the default text editor, type the following at a shell prompt:

```
~]$ git config --global core.editor vim
```

### Setting Up User Information

In **Git**, each commit (or revision) is associated with the full name and email of the person responsible for it. By default, **Git** uses an identity based on the user name and the host name.

To change the full name associated with your **Git** commits, type the following at a shell prompt:

```
git config --global user.name "full name"
```

To change the email address associated with your **Git** commits, type:

```
git config --global user.email "email_address"
```

### Example 2.23. Setting Up User Information

To configure **Git** to use **John Doe** as your full name and **john@example.com** as your email address, type the following at a shell prompt:

```
~]$ git config --global user.name "John Doe"  
~]$ git config --global user.email "john@example.com"
```

## 2.3.2. Creating a New Repository

A *repository* is a place where **Git** stores all files that are under revision control, as well as additional data related to these files, such as the complete history of changes or information about who made those changes and when. Unlike in centralized revision control systems like Subversion or CVS, a **Git** repository and a *working directory* are usually the same. A typical **Git** repository also only stores a single project and when publicly accessible, it allows anyone to create its clone with a complete revision history.

### Initializing an Empty Repository

To create a new, empty **Git** repository, change to the directory in which you want to keep the repository and type the following at a shell prompt:

```
git init
```

This creates a hidden directory named **.git** in which all repository information is stored.

### Importing Data to a Repository

To put an existing project under revision control, create a **Git** repository in the directory with the project and run the following command:

```
git add .
```

This marks all files and directories in the current working directory as ready to be added to the **Git** repository. To proceed and actually add this content to the repository, commit the changes by typing the following at a shell prompt:

```
git commit [-m "commit message"]
```

Replace *commit message* with a short description of your revision. If you omit the `-m` option, this command allows you to write the commit message in an external text editor. For information on how to configure the default text editor, see [Section 2.3.1, “Configuring the Default Text Editor”](#).

### 2.3.3. Cloning an Existing Repository

To clone an existing **Git** repository, type the following at a shell prompt:

```
git clone git_repository [directory]
```

Replace *git\_repository* with a URL or a path to the **Git** repository you want to clone, and *directory* with a path to the directory in which you want to store the clone.

### 2.3.4. Adding, Renaming, and Deleting Files

#### Adding Files and Directories

To add an existing file to a **Git** repository and put it under revision control, change to the directory with your local **Git** repository and type the following at a shell prompt:

```
git add file...
```

Replace *file* with the file or files you want to add. This command marks the selected file or files as ready to be added to the **Git** repository. Similarly, to add all files that are stored in a certain directory to a **Git** repository, type:

```
git add directory...
```

Replace *directory* with the directory or directories you want to add. This command marks all files in the selected directory or directories as ready to be added to the **Git** repository.

To proceed and actually add this content to the repository, commit the changes as described in [Section 2.3.6, “Committing Changes”](#).

#### Renaming Files and Directories

To rename an existing file or directory in a **Git** repository, change to the directory with your local **Git** repository and type the following at a shell prompt:

```
git mv old_name new_name
```

Replace *old\_name* with the current name of the file or directory and *new\_name* with the new name. This command renames the selected file or directory and marks it as ready to be renamed in the **Git** repository.

To proceed and actually rename the content in the repository, commit the changes as described in [Section 2.3.6, “Committing Changes”](#).

## Deleting Files and Directories

To delete an existing file from a **Git** repository, change to the directory with your local **Git** repository and type the following at a shell prompt:

```
git rm file...
```

Replace *file* with the file or files you want to delete. This command deletes all selected files and marks them as ready to be deleted from the **Git** repository. Similarly, to delete all files that are stored in a certain directory from a **Git** repository, type:

```
git rm -r directory...
```

Replace *directory* with the directory or directories you want to delete. This command deletes all selected directories and marks them as ready to be deleted from the **Git** repository.

To proceed and actually delete this content from the repository, commit the changes as described in [Section 2.3.6, “Committing Changes”](#).

## 2.3.5. Viewing Changes

### Viewing the Current Status

To determine the current status of your local **Git** repository, change to the directory with the repository and type the following command at a shell prompt:

```
git status
```

This command displays information about all uncommitted changes in the repository (**new file**, **renamed**, **deleted**, or **modified**) and tells you which changes will be applied the next time you commit them. For information on how to commit your changes, see [Section 2.3.6, “Committing Changes”](#).

### Viewing Differences

To view all changes in a **Git** repository, change to the directory with the repository and type the following at a shell prompt:

```
git diff
```

This command displays changes between the files in the repository and their latest revision. If you are only interested in changes in a particular file, supply its name on the command line as follows:

```
git diff file...
```

Replace *file* with the file or files you want to view.

## 2.3.6. Committing Changes

To apply your changes to a **Git** repository and create a new revision, change to the directory with the repository and type the following command at a shell prompt:

```
git commit [-m "commit message"]
```

Replace *commit message* with a short description of your revision. This command commits all changes in files that are explicitly marked as ready to be committed. To commit changes in all files that are under revision control, add the **-a** command line option as follows:

```
git commit -a [-m "commit message"]
```

Note that if you omit the **-m** option, the command allows you to write the commit message in an external text editor. For information on how to configure the default text editor, see [Section 2.3.1, "Configuring the Default Text Editor"](#).

### 2.3.7. Sharing Changes

Unlike in centralized version control systems such as CVS or Subversion, when working with **Git**, project contributors usually do not make their changes in a single, central repository. Instead, they either create a publicly accessible clone of their local repository, or submit their changes to others over email as patches.

#### Pushing Changes to a Public Repository

To push your changes to a publicly accessible **Git** repository, change to the directory with your local repository and type the following at a shell prompt:

```
git push remote_repository
```

Replace *remote\_repository* with the name of the remote repository you want to push your changes to. Note that the repository from which you originally cloned your local copy is automatically named **origin**.

#### Creating Patches from Individual Commits

To create patches from your commits, change to the directory with your local **Git** repository and type the following at a shell prompt:

```
git format-patch remote_repository
```

Replace *remote\_repository* with the name of the remote repository from which you made your local copy. This creates a patch for each commit that is not present in this remote repository.

### 2.3.8. Updating a Repository

To update your local copy of a **Git** repository and get the latest changes from a remote repository, change to the directory with your local **Git** repository and type the following at a shell prompt:

```
git fetch remote_repository
```

Replace `remote_repository` with the name of the remote repository. This command fetches information about the current status of the remote repository, allowing you to review these changes before applying them to your local copy. To proceed and merge these changes with what you have in your local **Git** repository, type:

```
git merge remote_repository
```

Alternatively, you can perform both these steps at the same time by using the following command instead:

```
git pull remote_repository
```

### 2.3.9. Additional Resources

A detailed description of **Git** and its features is beyond the scope of this book. For more information about this revision control system, see the resources listed below.

#### Installed Documentation

- » **gittutorial(7)** — The manual page named **gittutorial** provides a brief introduction to **Git** and its usage.
- » **gittutorial-2(7)** — The manual page named **gittutorial-2** provides the second part of a brief introduction to **Git** and its usage.
- » *Git User's Manual* — HTML documentation for **Git** is located at `/usr/share/doc/git-1.7.1/user-manual.html`.

#### Online Documentation

- » [Pro Git](#) — The online version of the *Pro Git* book provides a detailed description of **Git**, its concepts and its usage.

# Chapter 3. Libraries and Runtime Support

Red Hat Enterprise Linux 6 supports the development of custom applications in a wide variety of programming languages using proven, industrial-strength tools. This chapter describes the runtime support libraries provided in Red Hat Enterprise Linux 6.

## 3.1. Version Information

The following table compares the version information for runtime support packages in supported programming languages between Red Hat Enterprise Linux 6, Red Hat Enterprise Linux 5, and Red Hat Enterprise Linux 4.

This is not an exhaustive list. Instead, this is a survey of standard language runtimes, and key dependencies for software developed on Red Hat Enterprise Linux 6.

**Table 3.1. Language and Runtime Library Versions**

Package Name	Red Hat Enterprise 6	Red Hat Enterprise 5	Red Hat Enterprise 4
<i>glibc</i>	2.12	2.5	2.3
<i>libstdc++</i>	4.4	4.1	3.4
<i>boost</i>	1.41	1.33	1.32
<i>java</i>	1.5 (IBM), 1.6 (IBM, OpenJDK, Oracle Java)	1.4, 1.5, and 1.6	1.4
<i>python</i>	2.6	2.4	2.3
<i>php</i>	5.3	5.1	4.3
<i>ruby</i>	1.8	1.8	1.8
<i>httpd</i>	2.2	2.2	2.0
<i>postgresql</i>	8.4	8.1	7.4
<i>mysql</i>	5.1	5.0	4.1
<i>nss</i>	3.12	3.12	3.12
<i>openssl</i>	1.0.0	0.9.8e	0.9.7a
<i>libX11</i>	1.3	1.0	
<i>firefox</i>	3.6	3.6	3.6
<i>kdebase</i>	4.3	3.5	3.3
<i>gtk2</i>	2.18	2.10	2.04

### Note

The **compat-glibc** RPM is included with Red Hat Enterprise Linux 6, but it is not a runtime package and therefore not required for running anything. It is solely a development package, containing header files and dummy libraries for linking. This allows compiling and linking packages to run in older Red Hat Enterprise Linux versions (using **compat-gcc-\*** against those headers and libraries). Running **rpm -qpi compat-glibc-\*** will provide some information on how to use this package.

For more information on **compat-glibc**, see [Section 3.3.1, “compat-glibc”](#)

## 3.2. Compatibility

Compatibility specifies the portability of binary objects and source code across different instances of a computer operating environment. Officially, Red Hat supports current release and two consecutive prior versions. This means that applications built on Red Hat Enterprise Linux 4 and Red Hat Enterprise Linux 5 will continue to run on Red Hat Enterprise Linux 6 as long as they comply with Red Hat guidelines (using the symbols that have been white-listed, for example).

Red Hat understands that as an enterprise platform, customers rely on long-term deployment of their applications. For this reason, applications built against C/C++ libraries with the help of compatibility libraries continue to be supported for ten years.

There are two types of compatibility:

### Source Compatibility

Source compatibility specifies that code will compile and execute in a consistent and predictable way across different instances of the operating environment. This type of compatibility is defined by conformance with specified Application Programming Interfaces (APIs).

### Binary Compatibility

Binary Compatibility specifies that compiled binaries in the form of executables and *Dynamic Shared Objects* (DSOs) will run correctly across different instances of the operating environment. This type of compatibility is defined by conformance with specified Application Binary Interfaces (ABIs).

For further information regarding this and all levels of compatibility between core and non-core libraries, see Red Hat Enterprise Linux supported releases accessed at

<https://access.redhat.com/support/policy/updates/errata/> and the general Red Hat Enterprise Linux compatibility policy, accessed at <https://access.redhat.com/solutions/5154>.

### 3.2.1. Static Linking

Static linking is emphatically discouraged for all Red Hat Enterprise Linux releases. Static linking causes far more problems than it solves, and should be avoided at all costs.

The main drawback of static linking is that it is only guaranteed to work on the system on which it was built, and even then only until the next release of glibc or libstdc++ (in the case of C++). There is no forward or backward compatibility with a static build. Furthermore, any security fixes (or general-purpose fixes) in subsequent updates to the libraries will not be available unless the affected statically linked executables are re-linked.

A few more reasons why static linking should be avoided are:

- » Larger memory footprint.
- » Slower application startup time.
- » Reduced glibc features with static linking.
- » Security measures like load address randomization cannot be used.
- » Dynamic loading of shared objects outside of glibc is not supported.

For additional reasons to avoid static linking, see: [Static Linking Considered Harmful](#).

## 3.3. Library and Runtime Details

### 3.3.1. compat-glibc

**compat-glibc** provides a subset of the shared static libraries from previous versions of Red Hat Enterprise Linux. For Red Hat Enterprise Linux 6, the following libraries are provided:

- » **libanl**
- » **libcidn**
- » **libcrypt**
- » **libc**
- » **libdl**
- » **libm**
- » **libnsl**
- » **libpthread**
- » **libresolv**
- » **librt**
- » **libthread\_db**
- » **libutil**

This set of libraries allows developers to create a Red Hat Enterprise Linux 5 application with Red Hat Enterprise Linux 6, provided the application uses only the above libraries. Use the following command to do so:

```
# gcc -fgnu89-inline -I /usr/lib/x86_64-redhat-linux5E/include -B /usr/lib/x86_64-redhat-linux5E/lib64/ -lc_nonshared
```

### 3.3.2. The GNU C++ Standard Library

The **libstdc++** package contains the GNU C++ Standard Library, which is an ongoing project to implement the ISO 14882 Standard C++ library.

Installing the **libstdc++** package will provide just enough to satisfy link dependencies (that is, only shared library files). To make full use of all available libraries and header files for C++ development, you must install **libstdc++-devel** as well. The **libstdc++-devel** package also contains a GNU-specific implementation of the Standard Template Library (STL).

For Red Hat Enterprise Linux 4, 5, and 6, the C++ language and runtime implementation has remained stable and as such no compatibility libraries are required for **libstdc++**. However, this is not the case for Red Hat Enterprise Linux 2 and 3. For Red Hat Enterprise Linux 2 **compat-libstdc++-296** is required to be installed. For Red Hat Enterprise Linux 3 **compat-libstdc++-33** is required to be installed. Neither of these are installed by default so have to be added separately.

#### 3.3.2.1. GNU C++ Standard Library Updates

The Red Hat Enterprise Linux 6 version of the GNU C++ Standard Library features the following improvements over its Red Hat Enterprise Linux 5 version:

- » Added support for elements of ISO C++ TR1, namely:
  - `<tr1/array>`
  - `<tr1/complex>`
  - `<tr1/memory>`
  - `<tr1/functional>`
  - `<tr1/random>`
  - `<tr1/regex>`
  - `<tr1/tuple>`
  - `<tr1/type_traits>`
  - `<tr1/unordered_map>`
  - `<tr1/unordered_set>`
  - `<tr1/utility>`
  - `<tr1/cmath>`
- » Added support for elements of the upcoming ISO C++ standard, C++0x. These elements include:
  - `<array>`
  - `<chrono>`
  - `<condition_variable>`
  - `<forward_list>`
  - `<functional>`
  - `<initializer_list>`
  - `<mutex>`
  - `<random>`
  - `<ratio>`
  - `<regex>`
  - `<system_error>`
  - `<thread>`
  - `<tuple>`
  - `<type_traits>`
  - `<unordered_map>`
  - `<unordered_set>`

- » Added support for the **-fvisibility** command.
- » Added the following extensions:
  - **\_\_gnu\_cxx::typelist**
  - **\_\_gnu\_cxx::throw\_allocator**

For more information about updates to **libstdc++** in Red Hat Enterprise Linux 6, see the C++ *Runtime Library* section of the following documents:

- » *GCC 4.2 Release Series Changes, New Features, and Fixes*: <http://gcc.gnu.org/gcc-4.2/changes.html>
- » *GCC 4.3 Release Series Changes, New Features, and Fixes*: <http://gcc.gnu.org/gcc-4.3/changes.html>
- » *GCC 4.4 Release Series Changes, New Features, and Fixes*: <http://gcc.gnu.org/gcc-4.4/changes.html>

### 3.3.2.2. GNU C++ Standard Library Documentation

To use the **man** pages for library components, install the **libstdc++-docs** package. This will provide **man** page information for nearly all resources provided by the library; for example, to view information about the **vector** container, use its fully-qualified component name:

```
man std::vector
```

This will display the following information (abbreviated):

```
std::vector(3)
std::vector(3)

NAME
    std::vector - 

    A standard container which offers fixed time access to individual
    elements in any order.

SYNOPSIS
    Inherits std::Vector_base< _Tp, _Alloc >.

    Public Types
        typedef _Alloc allocator_type
        typedef __gnu_cxx::__normal_iterator< const_pointer, vector >
            const_iterator
        typedef _Tp_alloc_type::const_pointer const_pointer
        typedef _Tp_alloc_type::const_reference const_reference
        typedef std::reverse_iterator< const_iterator >
```

The **libstdc++-docs** package also provides manuals and reference information in HTML form at the following directory:

```
file:///usr/share/doc/libstdc++-docs-version/html/spine.html
```

The main site for the development of libstdc++ is hosted on [gcc.gnu.org](http://gcc.gnu.org).

### 3.3.3. Boost

The **boost** package contains a large number of free peer-reviewed portable C++ source libraries. These libraries are suitable for tasks such as portable file-systems and time/date abstraction,

serialization, unit testing, thread creation and multi-process synchronization, parsing, graphing, regular expression manipulation, and many others.

Installing the **boost** package will provide just enough libraries to satisfy link dependencies (that is, only shared library files). To make full use of all available libraries and header files for C++ development, you must install **boost-devel** as well.

The **boost** package is actually a meta-package, containing many library sub-packages. These sub-packages can also be installed individually to provide finer inter-package dependency tracking. The meta-package includes all of the following sub-packages:

- » **boost-date-time**
- » **boost-filesystem**
- » **boost-graph**
- » **boost-iostreams**
- » **boost-math**
- » **boost-program-options**
- » **boost-python**
- » **boost-regex**
- » **boost-serialization**
- » **boost-signals**
- » **boost-system**
- » **boost-test**
- » **boost-thread**
- » **boost-wave**

Not included in the meta-package are packages for static linking or packages that depend on the underlying Message Passing Interface (MPI) support.

MPI support is provided in two forms: one for the default Open MPI implementation [1], and another for the alternate MPICH2 implementation. The selection of the underlying MPI library in use is up to the user and depends on specific hardware details and user preferences. Please note that these packages can be installed in parallel, as installed files have unique directory locations.

For Open MPI:

- » **boost-openmpi**
- » **boost-openmpi-devel**
- » **boost-graph-openmpi**
- » **boost-openmpi-python**

For MPICH2:

- » **boost-mpich2**
- » **boost-mpich2-devel**

- » **boost-graph-mpich2**
- » **boost-mpich2-python**

If static linkage cannot be avoided, the **boost-static** package will install the necessary static libraries. Both thread-enabled and single-threaded libraries are provided.

### 3.3.3.1. Boost Updates

The Red Hat Enterprise Linux 6 version of Boost features many packaging improvements and new features.

Several aspects of the **boost** package have changed. As noted above, the monolithic **boost** package has been augmented by smaller, more discrete sub-packages. This allows for more control of dependencies by users, and for smaller binary packages when packaging a custom application that uses Boost.

In addition, both single-threaded and multi-threaded versions of all libraries are packaged. The multi-threaded versions include the **mt** suffix, as per the usual Boost convention.

Boost also features the following new libraries:

- » Foreach
- » Statechart
- » TR1
- » Typeof
- » Xpressive
- » Asio
- » Bitmap
- » Circular Buffer
- » Function Types
- » Fusion
- » GIL
- » Interprocess
- » Intrusive
- » Math/Special Functions
- » Math/Statistical Distributions
- » MPI
- » System
- » Accumulators
- » Exception
- » Units

- » Unordered
- » Proto
- » Flyweight
- » Scope Exit
- » Swap
- » Signals2
- » Property Tree

Many of the existing libraries have been improved, bug-fixed, and otherwise enhanced.

### 3.3.3.2. Boost Documentation

The **boost-doc** package provides manuals and reference information in HTML form located in the following directory:

**file:///usr/share/doc/boost-doc-version/index.html**

The main site for the development of Boost is hosted on [boost.org](http://boost.org).

## 3.3.4. Qt

The **qt** package provides the Qt (pronounced "cute") cross-platform application development framework used in the development of GUI programs. Aside from being a popular "widget toolkit", Qt is also used for developing non-GUI programs such as console tools and servers. Qt was used in the development of notable projects such as Google Earth, KDE, Opera, OPIE, VoxOx, Skype, VLC media player and VirtualBox. It is produced by Nokia's Qt Development Frameworks division, which came into being after Nokia's acquisition of the Norwegian company Trolltech, the original producer of Qt, on June 17, 2008.

Qt uses standard C++ but makes extensive use of a special pre-processor called the *Meta Object Compiler* (MOC) to enrich the language. Qt can also be used in other programming languages via language bindings. It runs on all major platforms and has extensive internationalization support. Non-GUI Qt features include SQL database access, XML parsing, thread management, network support, and a unified cross-platform API for file handling.

Distributed under the terms of the GNU Lesser General Public License (among others), Qt is free and open source software. The Red Hat Enterprise Linux 6 version of Qt supports a wide range of compilers, including the GCC C++ compiler and the Visual Studio suite.

### 3.3.4.1. Qt Updates

Some of the improvements the Red Hat Enterprise Linux 6 version of Qt include:

- » Advanced user experience
  - **Advanced Graphics Effects:** options for opacity, drop-shadows, blur, colorization, and other similar effects
  - **Animation and State Machine:** create simple or complex animations without the hassle of managing complex code
  - Gesture and multi-touch support

- » Support for new platforms
  - Windows 7, Mac OSX 10.6, and other desktop platforms are now supported
  - Added support for mobile development; Qt is optimized for the upcoming Maemo 6 platform, and will soon be ported to Maemo 5. In addition, Qt now supports the Symbian platform, with integration for the S60 framework.
  - Added support for Real-Time Operating Systems such as QNX and VxWorks
- » Improved performance, featuring added support for hardware-accelerated rendering (along with other rendering updates)
- » Updated cross-platform IDE

For more details on updates to Qt included in Red Hat Enterprise Linux 6, see the following links:

- » <http://doc.qt.nokia.com/4.6/qt4-6-intro.html>
- » <http://doc.qt.nokia.com/4.6/qt4-intro.html>

### 3.3.4.2. Qt Creator

**Qt Creator** is a cross-platform IDE tailored to the requirements of Qt developers. It includes the following graphical tools:

- » An advanced C++ code editor
- » Integrated GUI layout and forms designer
- » Project and build management tools
- » Integrated, context-sensitive help system
- » Visual debugger
- » Rapid code navigation tools

### 3.3.4.3. Qt Library Documentation

The **qt-doc** package provides HTML manuals and references located in **/usr/share/doc/qt4/html/**. This package also provides the *Qt Reference Documentation*, which is an excellent starting point for development within the Qt framework.

You can also install further demos and examples from **qt-demos** and **qt-examples**. To get an overview of the capabilities of the Qt framework, see **/usr/bin/qtdemo-qt4** (provided by **qt-demos**).

## 3.3.5. KDE Development Framework

The **kdelibs-devel** package provides the KDE libraries, which build on Qt to provide a framework for making application development easier. The KDE development framework also helps provide consistency across the KDE desktop environment.

### 3.3.5.1. KDE4 Architecture

The KDE development framework's architecture in Red Hat Enterprise Linux 6 uses KDE4, which is built on the following technologies:

## Plasma

**Plasma** replaces KDesktop in KDE4. Its implementation is based on the **Qt Graphics View Framework**, which was introduced in Qt 4.2. For more information about **Plasma**, see <http://techbase.kde.org/Development/Architecture/KDE4/Plasma>.

## Sonnet

**Sonnet** is a multilingual spell-checking application that supports automatic language detection, primary/backup dictionaries, and other useful features. It replaces **kspell2** in KDE4.

## KIO

The KIO library provides a framework for network-transparent file handling, allowing users to easily access files through network-transparent protocols. It also helps provides standard file dialogs.

## KJS/KHTML

KJS and KHTML are fully-fledged JavaScript and HTML engines used by different applications native to KDE4 (such as **konqueror**).

## Solid

**Solid** is a hardware and network awareness framework that allows you to develop applications with hardware interaction features. Its comprehensive API provides the necessary abstraction to support cross-platform application development. For more information, see <http://techbase.kde.org/Development/Architecture/KDE4/Solid>.

## Phonon

**Phonon** is a multimedia framework that helps you develop applications with multimedia functionalities. It facilitates the usage of media capabilities within KDE. For more information, see <http://techbase.kde.org/Development/Architecture/KDE4/Phonon>.

## Telepathy

**Telepathy** provides a real-time communication and collaboration framework within KDE4. Its primary function is to tighten integration between different components within KDE. For a brief overview on the project, see [http://community.kde.org/Real-Time\\_Communication\\_and\\_Collaboration](http://community.kde.org/Real-Time_Communication_and_Collaboration).

## Akonadi

**Akonadi** provides a framework for centralizing storage of *Parallel Infrastructure Management* (PIM) components. For more information, see <http://techbase.kde.org/Development/Architecture/KDE4/Akonadi>.

## Online Help within KDE4

KDE4 also features an easy-to-use Qt-based framework for adding online help capabilities to applications. Such capabilities include tooltips, hover-help information, and **khelpcenter** manuals. For a brief overview on online help within KDE4, see [http://techbase.kde.org/Development/Architecture/KDE4/Providing\\_Online\\_Help](http://techbase.kde.org/Development/Architecture/KDE4/Providing_Online_Help).

## KXMLGUI

**KXMLGUI** is a framework for designing user interfaces using XML. This framework allows you to design UI elements based on "actions" (defined by the developer) without having to revise source code. For more information, see [https://techbase.kde.org/Development/Architecture/KDE3/XMLGUI\\_Technology](https://techbase.kde.org/Development/Architecture/KDE3/XMLGUI_Technology).

### Strigi

**Strigi** is a desktop search daemon compatible with many desktop environments and operating systems. It uses its own **jstream** system which allows for deep indexing of files. For more information on the development of **Strigi**, see <http://www.vandenoever.info/software/strigi/>.

### KNewStuff2

**KNewStuff2** is a collaborative data sharing library used by many KDE4 applications. For more information, see <http://techbase.kde.org/Projects/KNS2>.

## 3.3.5.2. kdelibs Documentation

The **kdelibs-apidocs** package provides HTML documentation for the KDE development framework in `/usr/share/doc/HTML/en/kdelibs4-apidocs/`. The following links also provide details on KDE-related programming tasks:

- » <http://techbase.kde.org/>
- » <http://techbase.kde.org/Development/Tutorials>
- » <http://techbase.kde.org/Development/FAQs>
- » <http://api.kde.org>

## 3.3.6. GNOME Power Manager

The backend program of the GNOME power management infrastructure is **gnome-power-manager**. It was introduced in Red Hat Enterprise Linux 5 and provides a complete and integrated solution to power management under the GNOME desktop environment. In Red Hat Enterprise Linux 6, the storage-handling parts of **hal** was replaced by **udisks**, and the **libgnomeprint** stack was replaced by print support in **gtk2**.

### 3.3.6.1. GNOME Power Management Version Guide

This section will detail what versions of **gnome-power-management** are shipped with the various Red Hat Enterprise Linux versions.

In general, however, Red Hat Enterprise Linux 4 ships with GNOME 2.8, Red Hat Enterprise Linux 5 ships with GNOME 2.16, and Red Hat Enterprise Linux 6 ships with GNOME 2.28.

**Table 3.2. Desktop Components Comparison**

	Red Hat Enterprise Linux Version		
	4	5	6
<b>GNOME Power Management Desktop Components</b>			
<i>hal</i>	0.4.2	0.5.8	0.5.14
<i>udisks</i>	N/A	N/A	1.0.1

<b>GNOME Power Management Desktop Components</b>	<b>Red Hat Enterprise Linux Version</b>		
	<b>4</b>	<b>5</b>	<b>6</b>
<i>glib2</i>	2.4.7	2.12.3	2.22.5
<i>gtk2</i>	2.4.13	2.10.4	2.18.9
<i>gnome-vfs2</i>	2.8.2	2.16.2	2.24.2
<i>libglade2</i>	2.4.0	2.6.0	2.6.4
<i>libgnomecanvas</i>	2.8.0	2.14.0	2.26.0
<i>gnome-desktop</i>	2.8.0	2.16.0	2.28.2
<i>gnome-media</i>	2.8.0	2.16.1	2.29.91
<i>gnome-python2</i>	2.6.0	2.16.0	2.28.0
<i>libgnome</i>	2.8.0	2.16.0	2.28.0
<i>libgnomeui</i>	2.8.0	2.16.0	2.24.1
<i>libgnomeprint22</i>	2.8.0	2.12.1	N/A
<i>libgnomeprintui22</i>	2.8.0	2.12.1	N/A
<i>gnome-session</i>	2.8.0	2.16.0	2.28.0
<i>gnome-power-manager</i>	N/A	2.16.0	2.28.3
<i>gnome-applets</i>	2.8.0	2.16.0	2.28.0
<i>gnome-panel</i>	2.8.1	2.16.1	2.30.2

### 3.3.6.2. API Changes for *glib*

There are a number of API changes for *glib* between versions.

#### Version 2.4 to Version 2.12

Some of the differences in *glib* between version 2.4 and 2.12 (or between Red Hat Enterprise Linux 4 and Red Hat Enterprise Linux 5) are:

- » GOption (a command line option parser)
- » GKeyFile (a key/ini file parser)
- » GObject toggle references
- » GMappedFile (a map wrapper)
- » GSlice (a fast memory allocator)
- » GBookmarkFile (a bookmark file parser)
- » Base64 encoding support
- » Native atomic ops on s390
- » Updated Unicode support to 5
- » Atomic reference counting for GObject

#### Version 2.12 to Version 2.22

Some of the differences in *glib* between version 2.12 and 2.22 (or between Red Hat Enterprise Linux 5 and Red Hat Enterprise Linux 6) are:

- » GSequence (a list data structure that is implemented as a balanced tree)
- » GRegex (a PCRE regex wrapper)
- » Support for monotonic clocks
- » XDG user dirs support
- » GIO (a VFS library to replace gnome-vfs)
- » GChecksum (support for hash algorithms such as MD5 and SHA-256)
- » GTest (a test framework)
- » Support for sockets and network IO in GIO
- » GHashTable performance improvements
- » GMarkup performance improvements

Documentation for *glib*, including indexes of new and deprecated APIs, is shipped in the *glib2-devel* package.

### 3.3.6.3. API Changes for GTK+

There are a number of API changes for GTK+ between versions.

#### Version 2.4 to Version 2.10

Some of the differences in GTK+ between version 2.4 and 2.10 (or between Red Hat Enterprise Linux 4 and Red Hat Enterprise Linux 5) are:

- » GtkIconView
- » GtkAboutDialog
- » GtkCellView
- » GtkFileChooserButton
- » GtkMenuToolButton
- » GtkAssistant
- » GtkLinkButton
- » GtkRecentChooser
- » GtkCellRendererCombo
- » GtkCellRendererProgress
- » GtkCellRendererAccel
- » GtkCellRendererSpin
- » GtkStatusIcon
- » Printing Support
- » Notebook tab DND support

- » Ellipsis support in labels, progressbars and treeviews
- » Support rotated text
- » Improved themability

### Version 2.10 to Version 2.18

Some of the differences in *GTK+* between version 2.10 and 2.18 (or between Red Hat Enterprise Linux 4 and Red Hat Enterprise Linux 5) are:

- » GtkScaleButton
- » GtkVolumeButton
- » GtkInfoBar
- » GtkBuilder to replace libglade
- » New tooltips API
- » GtkMountOperation
- » gtk\_show\_uri
- » Scale marks
- » Links in labels
- » Support runtime font configuration changes
- » Use GIO

Documentation for *GTK+*, including indexes of new and deprecated APIs, is shipped in the *gtk2-devel* package.

### 3.3.7. NSS Shared Databases

The NSS shared database format, introduced on NSS 3.12, is now available in Red Hat Enterprise Linux 6. This encompasses a number of new features and components to improve access and usability.

Included, is the NSS certificate and key database which are now sqlite-based and allow for concurrent access. The legacy **key3.db** and **cert8.db** are also replaced with new SQL databases called **key4.db** and **cert9.db**. These new databases will store PKCS #11 token objects, which are the same as what is currently stored in **cert8.db** and **key3.db**.

Having support for shared databases enables a system-wide NSS database. It resides in **/etc/pki/nssdb** where globally trusted CA certificates become accessible to all applications. The command **rv = NSS\_InitReadWrite("sql:/etc/pki/nssdb");** initializes NSS for applications. If the application is run with root privileges, then the system-wide database is available on a read and write basis. However, if it is run with normal user privileges it becomes read only.

Additionally, a PEM PKCS #11 module for NSS allows applications to load into memory certificates and keys stored in PEM-formatted files (for example, those produced by openssl).

#### 3.3.7.1. Backwards Compatibility

The binary compatibility guarantees made by NSS upstream are preserved in NSS for Red Hat

Enterprise Linux 6. This guarantee states that NSS used in Red Hat Enterprise Linux 6 is backwards compatible with all older NSS 3.x shared libraries. Therefore, a program linked with an older NSS 3.x shared library will work without recompiling or relinking, and any applications that restrict the use of NSS APIs to the NSS Public Functions remain compatible with future versions of the NSS shared libraries.

### 3.3.7.2. NSS Shared Databases Documentation

Mozilla's wiki page explains the system-wide database rationale in great detail and can be accessed [http://wiki.mozilla.org/NSS\\_Shared\\_DB\\_And\\_LINUX](http://wiki.mozilla.org/NSS_Shared_DB_And_LINUX).

## 3.3.8. Python

The **python** package adds support for the Python programming language. This package provides the object and cached bytecode files required to enable runtime support for basic Python programs. It also contains the **python** interpreter and the **pydoc** documentation tool. The **python-devel** package contains the libraries and header files required for developing Python extensions.

Red Hat Enterprise Linux also ships with numerous **python**-related packages. By convention, the names of these packages have a **python** prefix or suffix. Such packages are either library extensions or python bindings to an existing library. For instance, **dbus-python** is a Python language binding for D-Bus.

Note that both cached bytecode (\*.**pyc**/\*.**pyo** files) and compiled extension modules (\*.**so** files) are incompatible between Python 2.4 (used in Red Hat Enterprise Linux 5) and Python 2.6 (used in Red Hat Enterprise Linux 6). As such, you will be required to rebuild any extension modules you use that are not part of Red Hat Enterprise Linux.

### 3.3.8.1. Python Updates

The Red Hat Enterprise Linux 6 version of Python features various language changes. For information about these changes, see the following project resources:

- » What's New in Python 2.5: <http://docs.python.org/whatsnew/2.5.html>
- » What's New in Python 2.6: <http://docs.python.org/whatsnew/2.6.html>

Both resources also contain advice on porting code developed using previous Python versions.

### 3.3.8.2. Python Documentation

For more information about Python, see **man python**. You can also install **python-docs**, which provides HTML manuals and references in the following location:

**file:///usr/share/doc/python-docs-version/html/index.html**

For details on library and language components, use **pydoc component\_name**. For example, **pydoc math** will display the following information about the **math** Python module:

```
Help on module math:

NAME
    math

FILE
    /usr/lib64/python2.6/lib-dynload/mathmodule.so
```

**DESCRIPTION**

This module is always available. It provides access to the mathematical functions defined by the C standard.

**FUNCTIONS**

`acos[...]`  
`acos(x)`

Return the arc cosine (measured in radians) of `x`.

`acosh[...]`  
`acosh(x)`

Return the hyperbolic arc cosine (measured in radians) of `x`.

`asin(...)`  
`asin(x)`

Return the arc sine (measured in radians) of `x`.

`asinh[...]`  
`asinh(x)`

Return the hyperbolic arc sine (measured in radians) of `x`.

The main site for the Python development project is hosted on [python.org](http://python.org).

### 3.3.9. Java

The **java-1.6.0-openjdk** package adds support for the Java programming language. This package provides the **java** interpreter. The **java-1.6.0-openjdk-devel** package contains the **javac** compiler, as well as the libraries and header files required for developing Java extensions.

Red Hat Enterprise Linux also ships with numerous **java**-related packages. By convention, the names of these packages have a **java** prefix or suffix.

#### 3.3.9.1. Java Documentation

For more information about Java, see **man java**. Some associated utilities also have their own respective **man** pages.

You can also install other Java documentation packages for more details about specific Java utilities. By convention, such documentation packages have the **javadoc** suffix (for example, **dbus-java-javadoc**).

The main site for the development of Java is hosted on <http://openjdk.java.net/>. The main site for the library runtime of Java is hosted on <http://icedtea.classpath.org>.

### 3.3.10. Ruby

The **ruby** package provides the Ruby interpreter and adds support for the Ruby programming language. The **ruby-devel** package contains the libraries and header files required for developing Ruby extensions.

Red Hat Enterprise Linux also ships with numerous **ruby**-related packages. By convention, the names of these packages have a **ruby** or **rubygem** prefix or suffix. Such packages are either library extensions or Ruby bindings to an existing library.

Examples of **ruby**-related packages include:

- » ruby-flexmock
- » rubygem-flexmock
- » rubygems
- » ruby-irb
- » ruby-libguestfs
- » ruby-libs
- » ruby-qpidd
- » ruby-rdoc
- » ruby-ri
- » ruby-saslwrapper
- » ruby-static
- » ruby-tcltk

For information about updates to the Ruby language in Red Hat Enterprise Linux 6, see the following resources:

- » **file:///usr/share/doc/ruby-version/NEWS**
- » **file:///usr/share/doc/ruby-version/NEWS-version**

### 3.3.10.1. Ruby Documentation

For more information about Ruby, see **man ruby**. You can also install **ruby-docs**, which provides HTML manuals and references in the following location:

**file:///usr/share/doc/ruby-docs-version/**

The main site for the development of Ruby is hosted on <http://www.ruby-lang.org>. The <http://www.ruby-doc.org> site also contains Ruby documentation.

## 3.3.11. Perl

The **perl** package adds support for the Perl programming language. This package provides Perl core modules, the Perl Language Interpreter, and the PerlDoc tool.

Red Hat also provides various perl modules in package form; these packages are named with the **perl-\*** prefix. These modules provide stand-alone applications, language extensions, Perl libraries, and external library bindings.

### 3.3.11.1. Perl Updates

For a full list of the differences between the Perl versions see the following documents:

## Perl 5.12 Updates

Perl 5.12 has the following updates:

- » Perl conforms closer to the Unicode standard.
- » Experimental APIs allow Perl to be extended with "pluggable" keywords and syntax.
- » Perl will be able to keep accurate time well past the "Y2038" barrier.
- » Package version numbers can be directly specified in "package" statements.
- » Perl warns the user about the use of deprecated features by default.

The Perl 5.12 delta can be accessed at <http://perldoc.perl.org/perl5120delta.html>.

## Perl 5.14 Updates

Perl 5.14 has the following updates:

- » Unicode 6.0 support.
- » Improved support for IPv6.
- » Easier auto-configuration of the CPAN client.
- » A new /r flag that makes s/// substitutions non-destructive.
- » New regular expression flags to control whether matched strings should be treated as ASCII or Unicode.
- » New **package Foo { }** syntax.
- » Less memory and CPU usage than previous releases.
- » A number of bug fixes.

The Perl 5.14 delta can be accessed at <http://perldoc.perl.org/perl5140delta.html>.

## Perl 5.16 Updates

Perl 5.14 has the following updates:

- » Support for Unicode 6.1.
- » **\$\$** variable is writable.
- » Improved debugger.
- » Accessing Unicode database files directly is now deprecated; use *Unicode::UCD* instead.
- » *Version::Requirements* is deprecated in favor of *CPAN::Meta::Requirements*.
- » A number of perl4 libraries are removed:
  - *abbrev.pl*
  - *assert.pl*
  - *bigfloat.pl*
  - *bignum.pl*

- *bigrat.pl*
- *cacheout.pl*
- *complete.pl*
- *ctime.pl*
- *dotsh.pl*
- *exceptions.pl*
- *fastcwd.pl*
- *flush.pl*
- *getcwd.pl*
- *getopt.pl*
- *getopts.pl*
- *hostname.pl*
- *importenv.pl*
- *lib/find{,depth}.pl*
- *look.pl*
- *newgetopt.pl*
- *open2.pl*
- *open3.pl*
- *pwd.pl*
- *hellwords.pl*
- *stat.pl*
- *tainted.pl*
- *termcap.pl*
- *timelocal.pl*

The Perl 5.16 delta can be accessed at <http://perldoc.perl.org/perl5160delta.html>.

### 3.3.11.2. Installation

Perl's capabilities can be extended by installing additional modules. These modules come in the following forms:

#### Official Red Hat RPM

The official module packages can be installed with **yum** or **rpm** from the Red Hat Enterprise Linux repositories. They are installed to **/usr/share/perl5** and either **/usr/lib/perl5** for 32bit architectures or **/usr/lib64/perl5** for 64bit architectures.

#### Modules from CPAN

Use the **cpan** tool provided by the *perl-CPAN* package to install modules directly from the CPAN website. They are installed to **/usr/local/share/perl5** and either **/usr/local/lib/perl5** for 32bit architectures or **/usr/local/lib64/perl5** for 64bit architectures.

### Third party module package

Third party modules are installed to **/usr/share/perl5/vendor\_perl** and either **/usr/lib/perl5/vendor\_perl** for 32bit architectures or **/usr/lib64/perl5/vendor\_perl** for 64bit architectures.

### Custom module package / manually installed module

These should be placed in the same directories as third-party modules. That is, **/usr/share/perl5/vendor\_perl** and either **/usr/lib/perl5/vendor\_perl** for 32bit architectures or **/usr/lib64/perl5/vendor\_perl** for 64bit architectures.

#### Warning

If an official version of a module is already installed, installing its non-official version can create conflicts in the **/usr/share/man** directory.

### 3.3.11.3. Perl Documentation

The **perldoc** tool provides documentation on language and core modules. To learn more about a module, use **perldoc module\_name**. For example, **perldoc CGI** will display the following information about the CGI core module:

```

NAME
    CGI - Handle Common Gateway Interface requests and responses

SYNOPSIS
    use CGI;

    my $q = CGI->new;

    [...]

DESCRIPTION
    CGI.pm is a stable, complete and mature solution for processing and
    preparing HTTP requests and responses. Major features including
    processing form submissions, file uploads, reading and writing cookies,
    query string generation and manipulation, and processing and preparing
    HTTP headers. Some HTML generation utilities are included as well.

    [...]

PROGRAMMING STYLE
    There are two styles of programming with CGI.pm, an object-oriented
    style and a function-oriented style. In the object-oriented style you
    create one or more CGI objects and then use object methods to create the

```

various elements of the page. Each CGI object starts out with the list of named parameters that were passed to your CGI script by the server.

[...]

For details on Perl functions, use **perldoc -f *function\_name***. For example, perldoc -f split will display the following information about the split function:

```
split /PATTERN/,EXPR,LIMIT
split /PATTERN/,EXPR
split /PATTERN/
split    Splits the string EXPR into a list of strings and returns
that list. By default, empty leading fields are preserved, and empty
trailing ones are deleted. (If all fields are empty, they are considered
to be trailing.)
```

In scalar context, returns the number of fields found. In scalar and void context it splits into the `@_` array. Use of `split` in scalar and void context is deprecated, however, because it clobbers your subroutine arguments.

If EXPR is omitted, splits the `$_` string. If PATTERN is also omitted, splits on whitespace (after skipping any leading whitespace). Anything matching PATTERN is taken to be a delimiter separating the fields. (Note that the delimiter may be longer than one character.)

[...]

Current PerlDoc documentation can be found on [perldoc.perl.org](http://perldoc.perl.org).

Core and external modules are documented on the [Comprehensive Perl Archive Network](http://comprehensive.perlarchive.net).

---

[1] MPI support is not available on IBM System Z machines (where Open MPI is not available).

## Chapter 4. Compiling and Building

Red Hat Enterprise Linux 6 includes many packages used for software development, including tools for compiling and building source code. This chapter discusses several of these packages and tools used to compile source code.

### 4.1. GNU Compiler Collection (GCC)

The GNU Compiler Collection (GCC) is a set of tools for compiling a variety of programming languages (including C, C++, ObjectiveC, ObjectiveC++, Fortran, and Ada) into highly optimized machine code. These tools include various compilers (like **gcc** and **g++**), run-time libraries (like **libgcc**, **libstdc++**, **libgfortran**, and **libgomp**), and miscellaneous other utilities.

#### 4.1.1. GCC Status and Features

GCC for Red Hat Enterprise Linux 6 is based on the 4.4.x release series and includes several bug fixes, enhancements, and backports from upcoming releases (including the GCC 4.5). However, GCC 4.5 was not considered sufficiently mature for an enterprise distribution when Red Hat Enterprise Linux 6 features were frozen.

This standardization means that as updates to the 4.4 series become available (4.4.1, 4.4.2, and so on), they will be incorporated into the compiler included with Red Hat Enterprise Linux 6 as updates. Red Hat may import additional backports and enhancements from upcoming releases outside the 4.4 series that will not break compatibility within the Enterprise Linux release. Occasionally, code that was not compliant to standards may fail to compile or its functionality may change in the process of fixing bugs or maintaining standards compliant behavior.

Since the previous release of Red Hat Enterprise Linux, GCC has had three major releases: 4.2.x, 4.3.x, and 4.4.x. A selective summary of the expansive list of changes follows.

- » The inliner, dead code elimination routines, compile time, and memory usage codes are now improved. This release also features a new register allocator, instruction scheduler, and software pipeliner.
- » Version 3.0 of the OpenMP specification is now supported for the C, C++, and Fortran compilers.
- » Experimental support for the upcoming ISO C++ standard (C++0x) is included. This has support for auto/inline namespaces, character types, and scoped enumerations. To enable this, use the compiler options **-std=c++0x** (which disables GNU extensions) or **-std=gnu++0x**.

For a more detailed list of the status of C++0x improvements, see:

[http://gcc.gnu.org/gcc-4.4/cxx0x\\_status.html](http://gcc.gnu.org/gcc-4.4/cxx0x_status.html)

- » GCC now incorporates the *Variable Tracking at Assignments* (VTA) infrastructure. This allows GCC to better track variables during optimizations so that it can produce improved debugging information (that is, DWARF) for the GNU Project Debugger, SystemTap, and other tools. For a brief overview of VTA, see [Section 5.4, “Variable Tracking at Assignments”](#).

With VTA you can debug optimized code drastically better than with previous GCC releases, and you do not have to compile with -O0 to provide a better debugging experience.

- » Fortran 2008 is now supported, while support for Fortran 2003 is extended.

For a more detailed list of improvements in GCC, see:

- » *Updates in the 4.2 Series:* <http://gcc.gnu.org/gcc-4.2/changes.html>

» *Updates in the 4.3 Series:* <http://gcc.gnu.org/gcc-4.3/changes.html>

» *Updates in the 4.4 Series:* <http://gcc.gnu.org/gcc-4.4/changes.html>

In addition to the changes introduced via the GCC 4.4 rebase, the Red Hat Enterprise Linux 6 version of GCC also features several fixes and enhancements backported from upstream sources (that is, version 4.5 and beyond). These improvements include the following (among others):

- » Improved DWARF3 debugging for debugging optimized C++ code.
- » Fortran optimization improvements.
- » More accurate instruction length information for ix86, Intel 64 and AMD64, and s390.
- » Intel Atom support.
- » POWER7 support.
- » C++ raw string support, u/U/u8 string literal support.

### 4.1.2. Language Compatibility

Application Binary Interfaces specified by the GNU C, C++, Fortran and Java Compiler include:

- » Calling conventions. These specify how arguments are passed to functions and how results are returned from functions.
- » Register usage conventions. These specify how processor registers are allocated and used.
- » Object file formats. These specify the representation of binary object code.
- » Size, layout, and alignment of data types. These specify how data is laid out in memory.
- » Interfaces provided by the runtime environment. Where the documented semantics do not change from one version to another they must be kept available and use the same name at all times.

The default system C compiler included with Red Hat Enterprise Linux 6 is largely compatible with the C99 ABI standard. Deviations from the C99 standard in GCC 4.4 are tracked [online](#).

In addition to the C ABI, the Application Binary Interface for the GNU C++ Compiler specifies the binary interfaces required to support the C++ language, such as:

- » Name mangling and demangling
- » Creation and propagation of exceptions
- » Formatting of run-time type information
- » Constructors and destructors
- » Layout, alignment, and padding of classes and derived classes
- » Virtual function implementation details, such as the layout and alignment of virtual tables

The default system C++ compiler included with Red Hat Enterprise Linux 6 conforms to the C++ ABI defined by the [Itanium C++ ABI \(1.86\)](#).

Although every effort has been made to keep each version of GCC compatible with previous releases, some incompatibilities do exist.

### ABI incompatibilities between Red Hat Enterprise Linux 6 and Red Hat

## Enterprise Linux 5

The following is a list of known incompatibilities between the Red Hat Enterprise Linux 6 and 5 toolchains.

- Passing/returning structs with flexible array members by value changed in some cases on Intel 64 and AMD64.
- Passing/returning of unions with long double members by value changed in some cases on Intel 64 and AMD64.
- Passing/returning structs with complex float member by value changed in some cases on Intel 64 and AMD64.
- Passing of 256-bit vectors on x86, Intel 64 and AMD64 platforms changed when `-mavx` is used.
- There have been multiple changes in passing of `_Decimal{32,64,128}` types and aggregates containing those by value on several targets.
- Packing of packed char bitfields changed in some cases.

## ABI incompatibilities between Red Hat Enterprise Linux 5 and Red Hat Enterprise Linux 4

The following is a list of known incompatibilities between the Red Hat Enterprise Linux 5 and 4 toolchains.

- There have been changes in the library interface specified by the C++ ABI for thread-safe initialization of function-scope static variables.
- On Intel 64 and AMD64, the medium model for building applications where data segment exceeds 4GB, was redesigned to match the latest ABI draft at the time. The ABI change results in incompatibility among medium model objects.

The compiler flag `-Wabi` can be used to get diagnostics indicating where these constructs appear in source code, though it will not catch every single case. This flag is especially useful for C++ code to warn whenever the compiler generates code that is known to be incompatible with the vendor-neutral C++ ABI.

Excluding the incompatibilities listed above, the GCC C and C++ language ABIs are *mostly* ABI compatible. The vast majority of source code will not encounter any of the known issues, and can be considered compatible.

Compatible ABIs allow the objects created by compiling source code to be portable to other systems. In particular, for Red Hat Enterprise Linux, this allows for *upward* compatibility. Upward compatibility is defined as the ability to link shared libraries and objects, created using a version of the compilers in a particular Red Hat Enterprise Linux release, with no problems. This includes new objects compiled on subsequent Red Hat Enterprise Linux releases.

The C ABI is considered to be stable, and has been so since at least Red Hat Enterprise Linux 3 (again, barring any incompatibilities mentioned in the above lists). Libraries built on Red Hat Enterprise Linux 3 and later can be linked to objects created on a subsequent environment (Red Hat Enterprise Linux 4, Red Hat Enterprise Linux 5, and Red Hat Enterprise Linux 6).

The C++ ABI is considered to be stable, but less stable than the C ABI, and only as of Red Hat Enterprise Linux 4 (corresponding to GCC version 3.4 and above.). As with C, this is only an upward compatibility. Libraries built on Red Hat Enterprise Linux 4 and above can be linked to objects created on a subsequent environment (Red Hat Enterprise Linux 5, and Red Hat Enterprise Linux 6).

To force GCC to generate code compatible with the C++ ABI in Red Hat Enterprise Linux releases

prior to Red Hat Enterprise Linux 4, some developers have used the **-fabi-version=1** option. This practice is not recommended. Objects created this way are indistinguishable from objects conforming to the current stable ABI, and can be linked (incorrectly) amongst the different ABIs, especially when using new compilers to generate code to be linked with old libraries that were built with tools prior to Red Hat Enterprise Linux 4.

### Warning

The above incompatibilities make it incredibly difficult to maintain ABI shared library sanity between releases, especially when developing custom libraries with multiple dependencies outside of the core libraries. Therefore, if shared libraries are developed, it is *highly* recommended that a new version is built for each Red Hat Enterprise Linux release.

#### 4.1.3. Object Compatibility and Interoperability

Two items that are important are the changes and enhancements in the underlying tools used by the compiler, and the compatibility between the different versions of a language's compiler.

Changes and new features in tools like **ld** (distributed as part of the **binutils** package) or in the dynamic loader (**ld.so**, distributed as part of the **glibc** package) can subtly change the object files that the compiler produces. These changes mean that object files moving to the current release of Red Hat Enterprise Linux from previous releases may lose functionality, behave differently at runtime, or otherwise interoperate in a diminished capacity. Known problem areas include:

- » **ld --build-id**

In Red Hat Enterprise Linux 6 this is passed to **ld** by default, whereas Red Hat Enterprise Linux 5 **ld** doesn't recognize it.

- » **as .cfi\_sections** support

In Red Hat Enterprise Linux 6 this directive allows **.debug\_frame**, **.eh\_frame** or both to be omitted from **.cfi\*** directives. In Red Hat Enterprise Linux 5 only **.eh\_frame** is omitted.

- » **as, ld, ld.so, and gdb STB\_GNU\_UNIQUE and %gnu\_unique\_symbol** support

In Red Hat Enterprise Linux 6 more debug information is generated and stored in object files. This information relies on new features detailed in the **DWARF** standard, and also on new extensions not yet standardized. In Red Hat Enterprise Linux 5, tools like **as**, **ld**, **gdb**, **objdump**, and **readelf** may not be prepared for this new information and may fail to interoperate with objects created with the newer tools. In addition, Red Hat Enterprise Linux 5 produced object files do not support these new features; these object files may be handled by Red Hat Enterprise Linux 6 tools in a sub-optimal manner.

An outgrowth of this enhanced debug information is that the debuginfo packages that ship with system libraries allow you to do useful source level debugging into system libraries if they are installed. See [Section 5.2, “Installing Debuginfo Packages”](#) for more information on debuginfo packages.

Object file changes, such as the ones listed above, may interfere with the portable use of **prelink**.

#### 4.1.4. Backwards Compatibility Packages

Several packages are provided to serve as an aid for those moving source code or executables from older versions of Red Hat Enterprise Linux to the current release. These packages are intended to be

used as a temporary aid in transitioning sources to newer compilers with changed behavior, or as a convenient way to otherwise isolate differences in the system environment from the compile environment.

## Note

Please be advised that Red Hat may remove these packages in future Red Hat Enterprise Linux releases.

The following packages provide compatibility tools for compiling Fortran or C++ source code on the current release of Red Hat Enterprise Linux 6 as *if one was using the older compilers on Red Hat Enterprise Linux 4:*

- » **compat-gcc-34**
- » **compat-gcc-34-c++**
- » **compat-gcc-34-g77**

The following package provides a compatibility runtime library for Fortran executables *compiled on Red Hat Enterprise Linux 5* to run without recompilation on the current release of Red Hat Enterprise Linux 6:

- » **compat-libgfortran-41**

Please note that backwards compatibility library packages are not provided for all supported system libraries, just the system libraries pertaining to the compiler and the C/C++ standard libraries.

For more information about backwards compatibility library packages, see the *Application Compatibility* section of the Red Hat Enterprise Linux 6 *Migration Guide*.

### 4.1.5. Previewing Red Hat Enterprise Linux 6 compiler features on Red Hat Enterprise Linux 5

On Red Hat Enterprise Linux 5, we have included the package **gcc44** as an update. This is a backport of the Red Hat Enterprise Linux 6 compiler to allow users running Red Hat Enterprise Linux 5 to compile their code with the Red Hat Enterprise Linux 6 compiler and experiment with new features and optimizations before upgrading their systems to the next major release. The resulting binary will be forward compatible with Red Hat Enterprise Linux 6, so it can be compiled on Red Hat Enterprise Linux 5 with **gcc44** and run on Red Hat Enterprise Linux 5, Red Hat Enterprise Linux 6, and above.

The Red Hat Enterprise Linux 5 **gcc44** compiler will be kept reasonably in step with the GCC 4.4.x that we ship with Red Hat Enterprise Linux 6 to ease transition. Though, to get the latest features, it is recommended Red Hat Enterprise Linux 6 is used for development. The **gcc44** is only provided as an aid in the conversion process.

### 4.1.6. Running GCC

To compile using GCC tools, first install **binutils** and **gcc**; doing so will also install several dependencies.

In brief, the tools work via the **gcc** command. This is the main driver for the compiler. It can be used from the command line to pre-process or compile a source file, link object files and libraries, or perform a combination thereof. By default, **gcc** takes care of the details and links in the provided **libgcc** library.

The compiler functions provided by GCC are also integrated into the Eclipse IDE as part of the **CDT**. This presents many advantages, particularly for developers who prefer a graphical interface and fully integrated environment.

Conversely, using GCC tools from the command line interface consumes less system resources. This also allows finer-grained control over compilers; GCC's command line tools can even be used outside of the graphical mode (runlevel 5).

#### 4.1.6.1. Simple C Usage

Basic compilation of a C language program using GCC is easy. Start with the following simple program:

##### **hello.c**

```
#include <stdio.h>

int main ()
{
    printf ("Hello world!\n");
    return 0;
}
```

The following procedure illustrates the compilation process for C in its most basic form.

##### **Procedure 4.1. Compiling a 'Hello World' C Program**

1. Compile **hello.c** into an executable with:

```
gcc hello.c -o hello
```

Ensure that the resulting binary **hello** is in the same directory as **hello.c**.

2. Run the **hello** binary, that is, **hello**.

#### 4.1.6.2. Simple C++ Usage

Basic compilation of a C++ language program using GCC is similar. Start with the following simple program:

##### **hello.cc**

```
#include <iostream>

using namespace std;

int main(void)
```

```
{
    cout << "Hello World!" << endl;
    return 0;
}
```

The following procedure illustrates the compilation process for C++ in its most basic form.

#### **Procedure 4.2. Compiling a 'Hello World' C++ Program**

1. Compile [hello.cc](#) into an executable with:

```
g++ hello.cc -o hello
```

Ensure that the resulting binary **hello** is in the same directory as **hello.cc**.

2. Run the **hello** binary, that is, **hello**.

#### **4.1.6.3. Simple Multi-File Usage**

To use basic compilation involving multiple files or object files, start with the following two source files:

##### **one.c**

```
#include <stdio.h>
void hello()
{
    printf("Hello world!\n");
}
```

##### **two.c**

```
extern void hello();

int main()
{
    hello();
    return 0;
}
```

The following procedure illustrates a simple, multi-file compilation process in its most basic form.

#### **Procedure 4.3. Compiling a Program with Multiple Source Files**

1. Compile [one.c](#) into an executable with:

```
gcc -c one.c -o one.o
```

Ensure that the resulting binary **one.o** is in the same directory as **one.c**.

2. Compile [two.c](#) into an executable with:

```
gcc -c two.c -o two.o
```

Ensure that the resulting binary **two . o** is in the same directory as **two . c**.

3. Compile the two object files **one . o** and **two . o** into a single executable with:

```
gcc one.o two.o -o hello
```

Ensure that the resulting binary **hello** is in the same directory as **one . o** and **two . o**.

4. Run the **hello** binary, that is, **hello**.

#### 4.1.6.4. Recommended Optimization Options

Different projects require different optimization options. There is no one-size-fits-all approach when it comes to optimization, but here are a few guidelines to keep in mind.

##### Instruction selection and tuning

It is very important to choose the correct architecture for instruction scheduling. By default GCC produces code optimized for the most common processors, but if the CPU on which your code will run is known, the corresponding **-mtune=** option to optimize the instruction scheduling, and **-march=** option to optimize the instruction selection should be used.

The option **-mtune=** optimizes instruction scheduling to fit your architecture by tuning everything except the ABI and the available instruction set. This option will not choose particular instructions, but instead will tune your program in such a way that executing on a particular architecture will be optimized. For example, if an Intel Core2 CPU will predominantly be used, choose **-mtune=core2**. If the wrong choice is made, the program will still run, but not optimally on the given architecture. The architecture on which the program will most likely run should always be chosen.

The option **-march=** optimizes instruction selection. As such, it is important to choose correctly as choosing incorrectly will cause your program to fail. This option selects the instruction set used when generating code. For example, if the program will be run on an AMD K8 core based CPU, choose **-march=k8**. Specifying the architecture with this option will imply **-mtune=**.

The **-mtune=** and **-march=** commands should only be used for tuning and selecting instructions within a given architecture, not to generate code for a different architecture (also known as cross-compiling). For example, this is not to be used to generate PowerPC code from an Intel 64 and AMD64 platform.

For a complete list of the available options for both **-march=** and **-mtune=**, see the GCC documentation available here: [GCC 4.4.4 Manual: Hardware Models and Configurations](#)

##### General purpose optimization flags

The compiler flag **-O2** is a good middle of the road option to generate fast code. It produces the best optimized code when the resulting code size is not large. Use this when unsure what would best suit.

When code size is not an issue, **-O3** is preferable. This option produces code that is slightly larger but runs faster because of a more frequent inline of functions. This is ideal for floating point intensive code.

The other general purpose optimization flag is **-Os**. This flag also optimizes for size, and produces faster code in situations where a smaller footprint will increase code locality, thereby reducing cache misses.

Use **-frecord-gcc-switches** when compiling objects. This records the options used to build objects into objects themselves. After an object is built, it determines which set of options were used to build it. The set of options are then recorded in a section called **.GCC.command.line** within the object and can be examined with the following:

```
$ gcc -frecord-gcc-switches -O3 -Wall hello.c -o hello
$ readelf --string-dump=.GCC.command.line hello

String dump of section '.GCC.command.line':
[     0] hello.c
[     8] -mtune=generic
[    17] -O3
[    1b] -Wall
[    21] -frecord-gcc-switches
```

It is very important to test and try different options with a representative data set. Often, different modules or objects can be compiled with different optimization flags in order to produce optimal results. See [Section 4.1.6.5, “Using Profile Feedback to Tune Optimization Heuristics”](#) for additional optimization tuning.

#### 4.1.6.5. Using Profile Feedback to Tune Optimization Heuristics

During the transformation of a typical set of source code into an executable, tens of hundreds of choices must be made about the importance of speed in one part of code over another, or code size as opposed to code speed. By default, these choices are made by the compiler using reasonable heuristics, tuned over time to produce the optimum runtime performance. However, GCC also has a way to teach the compiler to optimize executables for a specific machine in a specific production environment. This feature is called profile feedback.

Profile feedback is used to tune optimizations such as:

- » Inlining
- » Branch prediction
- » Instruction scheduling
- » Inter-procedural constant propagation
- » Determining of hot or cold functions

Profile feedback compiles a program first to generate a program that is run and analyzed and then a second time to optimize with the gathered data.

#### Procedure 4.4. Using Profile Feedback

1. The application must be instrumented to produce profiling information by compiling it with **-fprofile-generate**.
2. Run the application to accumulate and save the profiling information.
3. Recompile the application with **-fprofile-use**.

Step three will use the profile information gathered in step one to tune the compiler's heuristics while optimizing the code into a final executable.

#### Procedure 4.5. Compiling a Program with Profiling Feedback

1. Compile **source.c** to include profiling instrumentation:

```
gcc source.c -fprofile-generate -O2 -o executable
```

2. Run **executable** to gather profiling information:

**. /executable**

3. Recompile and optimize **source.c** with profiling information gathered in step one:

```
gcc source.c -fprofile-use -O2 -o executable
```

Multiple data collection runs, as seen in step two, will accumulate data into the profiling file instead of replacing it. This allows the executable in step two to be run multiple times with additional representative data in order to collect even more information.

The executable must run with representative levels of both the machine being used and a respective data set large enough for the input required. This ensures optimal results are achieved.

By default, GCC will generate the profile data into the directory where step one was performed. To generate this information elsewhere, compile with **-fprofile-dir=DIR** where **DIR** is the preferred output directory.

### Warning

The format of the compiler feedback data file changes between compiler versions. It is imperative that the program compilation is repeated with each version of the compiler.

#### 4.1.6.6. Using 32-bit compilers on a 64-bit host

On a 64-bit host, GCC will build executables that can only run on 64-bit hosts. However, GCC can be used to build executables that will run both on 64-bit hosts and on 32-bit hosts.

To build 32-bit binaries on a 64-bit host, first install 32-bit versions of any supporting libraries the executable may require. This must at least include supporting libraries for **glibc** and **libgcc**, and **libstdc++** if the program is a C++ program. On Intel 64 and AMD64, this can be done with:

```
yum install glibc-devel.i686 libgcc.i686 libstdc++-devel.i686
```

There may be cases where it is useful to install additional 32-bit libraries that a program may require. For example, if a program uses the **db4-devel** libraries to build, the 32-bit version of these libraries can be installed with:

```
yum install db4-devel.i686
```

### Note

The **.i686** suffix on the x86 platform (as opposed to **x86-64**) specifies a 32-bit version of the given package. For PowerPC architectures, the suffix is **ppc** (as opposed to **ppc64**).

After the 32-bit libraries have been installed, the **-m32** option can be passed to the compiler and linker to produce 32-bit executables. Provided the supporting 32-bit libraries are installed on the 64-bit system, this executable will be able to run on both 32-bit systems and 64-bit systems.

#### Procedure 4.6. Compiling a 32-bit Program on a 64-bit Host

1. On a 64-bit system, compile **hello.c** into a 64-bit executable with:

```
gcc hello.c -o hello64
```

2. Ensure that the resulting executable is a 64-bit binary:

```
$ file hello64
hello64: ELF 64-bit LSB executable, x86-64, version 1 (GNU/Linux),
dynamically linked (uses shared libs), for GNU/Linux 2.6.18, not
stripped
$ ldd hello64
linux-vdso.so.1 => (0x00007fff242dd000)
libc.so.6 => /lib64/libc.so.6 (0x00007f0721514000)
/lib64/ld-linux-x86-64.so.2 (0x00007f0721893000)
```

The command **file** on a 64-bit executable will include **ELF 64-bit** in its output, and **ldd** will list **/lib64/libc.so.6** as the main C library linked.

3. On a 64-bit system, compile **hello.c** into a 32-bit executable with:

```
gcc -m32 hello.c -o hello32
```

4. Ensure that the resulting executable is a 32-bit binary:

```
$ file hello32
hello32: ELF 32-bit LSB executable, Intel 80386, version 1
(GNU/Linux), dynamically linked (uses shared libs), for GNU/Linux
2.6.18, not stripped
$ ldd hello32
linux-gate.so.1 => (0x007eb000)
libc.so.6 => /lib/libc.so.6 (0x00b13000)
/lib/ld-linux.so.2 (0x00cd7000)
```

The command **file** on a 32-bit executable will include **ELF 32-bit** in its output, and **ldd** will list **/lib/libc.so.6** as the main C library linked.

If you have not installed the 32-bit supporting libraries you will get an error similar to this for C code:

```
$ gcc -m32 hello32.c -o hello32
/usr/bin/ld: crt1.o: No such file: No such file or directory
collect2: ld returned 1 exit status
```

A similar error would be triggered on C++ code:

```
$ g++ -m32 hello32.cc -o hello32-c++
In file included from /usr/include/features.h:385,
     from /usr/lib/gcc/x86_64-redhat-
linux/4.4.4/.../.../.../include/c++/4.4.4/x86_64-redhat-
linux/32/bits/os_defines.h:39,
     from /usr/lib/gcc/x86_64-redhat-
linux/4.4.4/.../.../.../include/c++/4.4.4/x86_64-redhat-
linux/32/bits/c++config.h:243,
     from /usr/lib/gcc/x86_64-redhat-
linux/4.4.4/.../.../.../include/c++/4.4.4/iostream:39,
     from hello32.cc:1:
/usr/include/gnu/stubs.h:7:27: error: gnu/stubs-32.h: No such file or
directory
```

These errors indicate that the supporting 32-bit libraries have not been properly installed as explained at the beginning of this section.

Also important is to note that building with `-m32` will not adapt or convert a program to resolve any issues arising from 32/64-bit incompatibilities. For tips on writing portable code and converting from 32-bits to 64-bits, see the paper entitled *Porting to 64-bit GNU/Linux Systems* in the [Proceedings of the 2003 GCC Developers Summit](#).

#### 4.1.7. GCC Documentation

For more information about GCC compilers, see the **man** pages for `cpp`, `gcc`, `g++`, `gcj`, and `gfortran`.

the following online user manuals are also available:

- » [GCC 4.4.4 Manual](#)
- » [GCC 4.4.4 GNU Fortran Manual](#)
- » [GCC 4.4.4 GCJ Manual](#)
- » [GCC 4.4.4 CPP Manual](#)
- » [GCC 4.4.4 GNAT Reference Manual](#)
- » [GCC 4.4.4 GNAT User's Guide](#)
- » [GCC 4.4.4 GNU OpenMP Manual](#)

The main site for the development of GCC is [gcc.gnu.org](#).

### 4.2. Distributed Compiling

Red Hat Enterprise Linux 6 also supports *distributed compiling*. This involves transforming one compile job into many smaller jobs; these jobs are distributed over a cluster of machines, which speeds up build time (particularly for programs with large codebases). The `distcc` package provides this capability.

To set up distributed compiling, install the following packages:

- » `distcc`
- » `distcc-server`

For more information about distributed compiling, see the **man** pages for `distcc` and `distccd`. The following link also provides detailed information about the development of `distcc`:

<http://code.google.com/p/distcc>

### 4.3. Autotools

GNU Autotools is a suite of command line tools that allow developers to build applications on different systems, regardless of the installed packages or even Linux distribution. These tools aid developers in creating a `configure` script. This script runs prior to builds and creates the top-level `Makefiles` required to build the application. The `configure` script may perform tests on the current system, create additional files, or run other directives as per parameters provided by the builder.

The Autotools suite's most commonly-used tools are:

**autoconf**

Generates the **configure** script from an input file (**configure.ac**, for example)

**automake**

Creates the **Makefile** for a project on a specific system

**autoscan**

Generates a preliminary input file (that is, **configure.scan**), which can be edited to create a final **configure.ac** to be used by **autoconf**

All tools in the Autotools suite are part of the **Development Tools** group package. You can install this package group to install the entire Autotools suite, or use **yum** to install any tools in the suite as you wish.

### 4.3.1. Autotools Plug-in for Eclipse

The Autotools suite is also integrated into the Eclipse IDE via the Autotools plug-in. This plug-in provides an Eclipse graphical user interface for Autotools, which is suitable for most C/C++ projects.

As of Red Hat Enterprise Linux 6, this plug-in only supports two templates for new C/C++ projects:

- » An empty project
- » A "hello world" application

The empty project template is used when importing projects into the C/C++ Development Toolkit that already support Autotools. Future updates to the Autotools plug-in will include additional graphical user interfaces (wizards, for example) for creating shared libraries and other complex scenarios.

The Red Hat Enterprise Linux 6 version of the Autotools plug-in also does not integrate **git** or **mercurial** into Eclipse. As such, Autotools projects that use **git** repositories will be required to be checked out *outside* the Eclipse workspace. Afterwards, you can specify the source location for such projects in Eclipse. Any repository manipulation (commits, or updates for example) are done via the command line.

### 4.3.2. Configuration Script

The most crucial function of Autotools is the creation of the **configure** script. This script tests systems for tools, input files, and other features it can use in order to build the project [2]. The **configure** script generates a **Makefile** which allows the **make** tool to build the project based on the system configuration.

To create the **configure** script, first create an input file. Then feed it to an Autotools utility in order to create the **configure** script. This input file is typically **configure.ac** or **Makefile.am**; the former is usually processed by **autoconf**, while the later is fed to **automake**.

If a **Makefile.am** input file is available, the **automake** utility creates a **Makefile** template (that is, **Makefile.in**), which may see information collected at configuration time. For example, the **Makefile** may have to link to a particular library *if and only if* that library is already installed. When the **configure** script runs, **automake** will use the **Makefile.in** templates to create a **Makefile**.

If a **configure.ac** file is available instead, then **autoconf** will automatically create the **configure** script based on the macros invoked by **configure.ac**. To create a preliminary **configure.ac**, use the **autoscan** utility and edit the file accordingly.

### 4.3.3. Autotools Documentation

Red Hat Enterprise Linux 6 includes **man** pages for **autoconf**, **automake**, **autoscan** and most tools included in the Autotools suite. In addition, the Autotools community provides extensive documentation on **autoconf** and **automake** on the following websites:

- » <http://www.gnu.org/software/autoconf/manual/autoconf.html>
- » <http://www.gnu.org/software/autoconf/manual/automake.html>

The following is an online book describing the use of Autotools. Although the above online documentation is the recommended and most up to date information on Autotools, this book is a good alternative and introduction.

- » <http://sourceware.org/autobook/>

For information on how to create Autotools input files, see:

- » <http://www.gnu.org/software/autoconf/manual/autoconf.html#Making-configure-Scripts>
- » <http://www.gnu.org/software/autoconf/manual/automake.html#Invoking-Automake>

The following upstream example also illustrates the use of Autotools in a simple **hello** program:

- » <http://www.gnu.org/software/hello/manual/hello.html>

## 4.4. Eclipse Built-in Specfile Editor

The Specfile Editor Plug-in for Eclipse provides useful features to help developers manage **.spec** files. This plug-in allows users to leverage several Eclipse GUI features in editing **.spec** files, such as auto-completion, highlighting, file hyperlinks, and folding.

In addition, the Specfile Editor Plug-in also integrates the **rpmlint** tool into the Eclipse interface. **rpmlint** is a command line tool that helps developers detect common RPM package errors. The richer visualization offered by the Eclipse interface helps developers quickly detect, view, and correct mistakes reported by **rpmlint**.

The Specfile Editor for Eclipse is provided by the **eclipse-rpm-editor** package. For more information about this plug-in, see *Specfile Editor User Guide* in the Eclipse **Help Contents**.

## 4.5. CDT in Eclipse

The **CDT** (C/C++ Development Tools) is an Eclipse project that adds support for developing C and C++ projects with Eclipse. A user can create three forms of projects:

1. Managed Make Project
2. Standard Make Project
3. Autotools Project

### 4.5.1. Managed Make Project

A managed make CDT project, sometimes referred to as a managed project, is one where the details regarding how to build the project are automated on behalf of the end-user. This differs from the standard make project, another common type of CDT C/C++ project, whereby a user supplies a Makefile that has the build details specified.

For a managed project, start by selecting the type of managed project and the required toolchain. The project type is categorized based on the ultimate target of the project, such as an executable, a shared library, or a static library. Within these categories there may be templates for more specific projects (a hello world sample executable project, for example) where base source files are already provided. These can then be further customized.

A toolchain is the set of tools used to generate the target. Typically, a Red Hat Enterprise Linux C/C++ developer would select the Linux GCC toolchain, which uses GCC for compiling, linking and assembly. Each tool in the toolchain is associated with one or more input types, typically specified by file suffix (for example, `.c` or `.h` or `.S`) or by file name. The tool will have parameter settings which can be customized by the developer, and each tool has an output type it creates. The tool also has a command or binary executable associated with it which may overlap among multiple tools. The C compiler and linker, for example, can both use GCC, but the compiler and linker tools will each have different input and output types, as well as different settings presented to the developer. Customize the tool settings through **Properties > C/C++ Build > Settings**. The toolchain itself can be customized in order to add, remove, or replace the used tools through **Properties > C/C++ Build > Toolchain Editor**.

New files, such as source files or header files, can be added to the project once it has been created. The new files are added automatically to the build based on their input types and the tool settings. Navigate to **Project > C/C++ Build** under the **Builder Settings** tab in order for the managed make project to generate a Makefile which can be distributed with the project. This facilitates the use of the Makefile outside Eclipse.

For more information regarding managed make C/C++ projects, see the *C/C++ Development User Guide* which can be found by navigating to **Concepts > Project Types, Tasks > Creating a Project**, or **Reference > C/C++ Properties > C/C++ Project Properties > C/C++ Build > Settings Page**.

#### 4.5.2. Standard Make Project

A standard make CDT project is a traditional C project with a Makefile that is manually managed by the developer. Unlike the managed make project, there are no tool settings to be used in determining rules in the Makefile. Manual additions to the Makefile are required when new source files that are to be processed as part of the build are added to the project. If a pattern rule exists which the new file name matches (for example, `.c : .o`, which states how to process a file with the suffix `.c` into a file with the suffix `.o`), then this is not required.

The default make target for building the project is **all**, and the default make target for cleaning the project is **clean**. It is also possible for a user to build other targets found in the Makefile. To do this use the Makefile Target dialog to create targets to run or build existing ones. Creating pseudo-targets that group multiple targets found in the makefile in a particular order is also done through the Makefile Target dialog. To access the specific create and build dialogs, select **Project > Make Target > Create...** and **Project > Make Target > Build...** respectively. Alternatively, right click on **resources** in the project and select the **Make Targets** option to access either **Create...** or **Build...**

For more information regarding standard make C/C++ projects, see the *C/C++ Development user guide*, accessed through **Concepts > Project Types, Tasks > Creating a project** or **Reference > C/C++ Properties > C/C++ Project Properties > C/C++Build > Settings Page**.

#### 4.5.3. Autotools Project

An autotools project is a lot like a standard make project however the Makefile is usually generated as part of a configuration step that occurs prior to building. See [Section 4.3, “Autotools”](#) for details on Autotools and the Autotools plug-in for Eclipse which adds support for this type of project. Like a standard make project, make targets can be run with the Make Target dialog.

## 4.6. build-id Unique Identification of Binaries

Each executable or shared library built with Red Hat Enterprise Linux Server 6 or later is assigned a unique identification 160-bit SHA-1 string, generated as a checksum of selected parts of the binary. This allows two builds of the same program on the same host to always produce consistent build-ids and binary content.

Display the build-id of a binary with the following command:

```
$ eu-readelf -n /bin/bash
[...]
Note section [ 3 ] '.note.gnu.build-id' of 36 bytes at offset 0x274:
  Owner   Data   size   Type
    GNU        20   GNU_BUILD_ID
Build ID: efdd0b5e69b0742fa5e5bad0771df4d1df2459d1
```

Unique identifiers of binaries are useful in cases such as analysing core files, documented [Section 5.2.1, “Installing Debuginfo Packages for Core Files Analysis”](#).

## 4.7. Software Collections and scl-utils

With Software Collections, it is possible to build and concurrently install multiple versions of the same RPM packages on a system. Software Collections have no impact on the system versions of the packages installed by the conventional RPM package manager.

To enable support for Software Collections on a system, install the packages *scl-utils* and by typing the following at a shell prompt as **root**:

```
~]# yum install scl-utils
```

The *scl-utils* package provides the **scl** tool, which is used to enable a Software Collection and to run applications in the Software Collection environment.

General usage of the **scl** tool can be described using the following syntax:

```
scl action software_collection_1 software_collection_2 command
```

### Example 4.1. Running an Application Directly

To directly run **Perl** with the **--version** option in the Software Collection named **software\_collection\_1**, execute the following command:

```
scl enable software_collection_1 'perl --version'
```

### Example 4.2. Running a Shell with Multiple Software Collections Enabled

To run the **Bash** shell in the environment with multiple Software Collections enabled, execute the following command:

```
scl enable software_collection_1 software_collection_2 bash
```

The command above enables two Software Collections named **software\_collection\_1** and **software\_collection\_2**.

#### **Example 4.3. Running Commands Stored in a File**

To execute a number of commands, which are stored in a file, in the Software Collections environment, run the following command:

```
cat cmd | scl enable software_collection_1 -
```

The above command executes commands, which are stored in the **cmd** file, in the environment of the Software Collection named **software\_collection\_1**.

For more information regarding Software Collections and **scl-utils**, see the [Red Hat Software Collections 1.2 Beta Packaging Guide](#).

[2] For information about tests that **configure** can perform, see the following link:

<http://www.gnu.org/software/autoconf/manual/autoconf.html#Existing-Tests>

# Chapter 5. Debugging

Useful, well-written software generally goes through several different phases of application development, allowing ample opportunity for mistakes to be made. Some phases come with their own set of mechanisms to detect errors. For example, during compilation an elementary semantic analysis is often performed to make sure objects, such as variables and functions, are adequately described.

The error-checking mechanisms performed during each application development phase aims to catch simple and obvious mistakes in code. The debugging phase helps to bring more subtle errors to light that fell through the cracks during routine code inspection.

## 5.1. ELF Executable Binaries

Red Hat Enterprise Linux uses ELF for executable binaries, shared libraries, or debuginfo files. Within these debuginfo ELF files, the DWARF format is used. Version 3 of DWARF is used in ELF files (that is, `gcc -g` is equivalent to `gcc -gdwarf-3`). DWARF debuginfo includes:

- » names of all the compiled functions and variables, including their target addresses in binaries
- » source files used for compilation, including their source line numbers
- » local variables location

### Important

STABS is occasionally used with UNIX. STABS is an older, less capable format. Its use is discouraged by Red Hat. GCC and GDB support STABS production and consumption on a best effort basis only.

Within these ELF files, the GCC debuginfo level is also used. The default is level 2, where macro information is not present; level 3 has C/C++ macro definitions included, but the debuginfo can be very large with this setting. The command for the default `gcc -g` is the same as `gcc -g2`. To change the macro information to level three, use `gcc -g3`.

There are multiple levels of debuginfo available. Use the command `readelf -WS file` to see which sections are used in a file.

**Table 5.1. debuginfo levels**

Binary State	Command	Notes
Stripped	<code>strip file</code> or <code>gcc -s -o file</code>	Only the symbols required for runtime linkage with shared libraries are present. ELF section in use: <code>.dynsym</code>
ELF symbols	<code>gcc -O file</code>	Only the names of functions and variables are present, no binding to the source files and no types. ELF section in use: <code>.symtab</code>

Binary State	Command	Notes
DWARF debuginfo with macros	<code>gcc -g -o file</code>	The source file names and line numbers are known, including types. ELF section in use: <code>.debug_*</code>
DWARF debuginfo with macros	<code>gcc -g3 -o file</code>	Similar to <code>gcc -g</code> but the macros are known to GDB. ELF section in use: <code>.debug_macro</code>

## Note

GDB never interprets the source files, it only displays them as text. Use `gcc -g` and its variants to store the information into DWARF.

Compiling a program or library with `gcc -rdynamic` is discouraged. For specific symbols, use `gcc -Wl, --dynamic-list=...` instead. If `gcc -rdynamic` is used, the `strip` command or `-s` gcc option have no effect. This is because all ELF symbols are kept in the binary for possible runtime linkage with shared libraries.

ELF symbols can be read by the `readelf -s file` command.

DWARF symbols are read by the `readelf -w file` command.

The command `readelf -wi file` is a good verification of debuginfo, compiled within your program. The commands `strip file` or `gcc -s` are commonly accidentally executed on the output during various compilation stages of the program.

The `readelf -w file` command can also be used to show a special section called `.eh_frame` with a format and purpose similar to the DWARF section `.debug_frame`. The `.eh_frame` section is used for runtime C++ exception resolution and is present even if `-g` gcc option was not used. It is kept in the primary RPM and is never present in the debuginfo RPMs.

Debuginfo RPMs contain the sections `.syms` and `.debug_*`. Neither `.eh_frame`, `.eh_frame_hdr`, nor `.dynsym` are moved or present in debuginfo RPMs as those sections are needed during program runtime.

## 5.2. Installing Debuginfo Packages

Red Hat Enterprise Linux also provides `-debuginfo` packages for all architecture-dependent RPMs included in the operating system. A `packagename-debuginfo-version-release.architecture.rpm` package contains detailed information about the relationship of the package source files and the final installed binary. The debuginfo packages contain both `.debug` files, which in turn contain DWARF debuginfo and the source files used for compiling the binary packages.

## Note

Most of the debugger functionality is missed if attempting to debug a package without having its debuginfo equivalent installed. For example, the names of exported shared library functions will still be available, but the matching source file lines will not be without the debuginfo package installed.

Use **gcc** compilation option **-g** for your own programs. The debugging experience is better if no optimizations (gcc option **-O**, such as **-O2**) is applied with **-g**.

For Red Hat Enterprise Linux 6, the debuginfo packages are now available on a new channel on the Red Hat Network. To install the **-debuginfo** package of a package (that is, typically **packagename-debuginfo**), first the machine has to be subscribed to the corresponding Debuginfo channel. For example, for Red Hat Enterprise Server 6, the corresponding channel would be **Red Hat Enterprise Linux Server Debuginfo (v. 6)**.

Red Hat Enterprise Linux system packages are compiled with optimizations (gcc option **-O2**). This means that some variables will be displayed as **<optimized out>**. Stepping through code will 'jump' a little but a crash can still be analyzed. If some debugging information is missing because of the optimizations, the right variable information can be found by disassembling the code and matching it to the source manually. This is applicable only in exceptional cases and is not suitable for regular debugging.

For system packages, GDB informs the user if it is missing some debuginfo packages that limit its functionality.

```
gdb ls
[...]
Reading symbols from /bin/ls...(no debugging symbols found)...done.
Missing separate debuginfos, use: debuginfo-install coreutils-8.4-
16.el6.x86_64
(gdb) q
```

If the system package to be debugged is known, use the command suggested by GDB above. It will also automatically install all the debug packages *packagename* depends on.

```
# debuginfo-install packagename
```

### 5.2.1. Installing Debuginfo Packages for Core Files Analysis

A core file is a representation of the memory image at the time of a process crash. For bug reporting of system program crashes, Red Hat recommends the use of the ABRT tool, explained in the *Automatic Bug Reporting Tool* chapter in the *Red Hat Deployment Guide*. If ABRT is not suitable for your purposes, the steps it automates are explained here.

If the **ulimit -c unlimited** setting is in use when a process crashes, the core file is dumped into the current directory. The core file contains only the memory areas modified by the process from the original state of disk files. In order to perform a full analysis of a crash, a core file is required to have:

- » the core file itself
- » the executable binary which has crashed, such as **/usr/sbin/sendmail**
- » all the shared libraries loaded in the binary when it crashed

- » .debug files and source files (both stored in debuginfo RPMs) for the executable and all of its loaded libraries

For a proper analysis, either the exact ***version-release.architecture*** for all the RPMs involved or the same build of your own compiled binaries is needed. At the time of the crash, the application may have already recompiled or been updated by **yum** on the disk, rendering the files inappropriate for the core file analysis.

The core file contains build-ids of all the binaries involved. For more information on build-id, see [Section 4.6, “build-id Unique Identification of Binaries”](#). The contents of the core file can be displayed by:

```
$ eu-unstrip -n --core=./core.9814
0x400000+0x207000 2818b2009547f780a5639c904cded443e564973e@0x400284
/bin/sleep /usr/lib/debug/bin/sleep.debug [exe]
0x7fff26fff000+0x1000
1e2a683b7d877576970e4275d41a6aaec280795e@0x7fff26fff340 . - linux-vdso.so.1
0x35e7e00000+0x3b6000
374add1ead31ccb449779bc7ee7877de3377e5ad@0x35e7e00280 /lib64/libc-
2.14.90.so /usr/lib/debug/lib64/libc-2.14.90.so.debug libc.so.6
0x35e7a00000+0x224000
3ed9e61c2b7e707ce244816335776afa2ad0307d@0x35e7a001d8 /lib64/ld-2.14.90.so
/usr/lib/debug/lib64/ld-2.14.90.so.debug ld-linux-x86-64.so.2
```

The meaning of the columns in each line are:

- » The in-memory address where the specific binary was mapped to (for example, **0x400000** in the first line).
- » The size of the binary (for example, **+0x207000** in the first line).
- » The 160-bit SHA-1 build-id of the binary (for example, **2818b2009547f780a5639c904cded443e564973e** in the first line).
- » The in-memory address where the build-id bytes were stored (for example, **@0x400284** in the first line).
- » The on-disk binary file, if available (for example, **/bin/sleep** in the first line). This was found by **eu-unstrip** for this module.
- » The on-disk debuginfo file, if available (for example, **/usr/lib/debug/bin/sleep.debug**). However, best practice is to use the binary file reference instead.
- » The shared library name as stored in the shared library list in the core file (for example, **libc.so.6** in the third line).

For each build-id (for example, **ab/cdef0123456789012345678901234567890123**) a symbolic link is included in its debuginfo RPM. Using the **/bin/sleep** executable above as an example, the **coreutils-debuginfo** RPM contains, among other files:

```
lrwxrwxrwx 1 root root 24 Nov 29 17:07 /usr/lib/debug/.build-
id/28/18b2009547f780a5639c904cded443e564973e -> ../../../../../../bin/sleep*
lrwxrwxrwx 1 root root 21 Nov 29 17:07 /usr/lib/debug/.build-
id/28/18b2009547f780a5639c904cded443e564973e.debug ->
../../../../bin/sleep.debug
```

In some cases (such as loading a core file), GDB does not know the name, version, or release of a **name-debuginfo-version-release.rpm** package; it only knows the build-id. In such cases,

GDB suggests a different command:

```
gdb -c ./core
[...]
Missing separate debuginfo for the main executable filename
Try: yum --disablerepo='*' --enablerepo='*debug*' install
/usr/lib/debug/.build-id/ef/dd0b5e69b0742fa5e5bad0771df4d1df2459d1
```

The *version-release.architecture* of the binary package *packagename-debuginfo-version-release.architecture.rpm* must be an exact match. If it differs then GDB cannot use the debuginfo package. Even the same *version-release.architecture* from a different build leads to an incompatible debuginfo package. If GDB reports a missing debuginfo, ensure to recheck:

**rpm -q *packagename* *packagename-debuginfo***

The *version-release.architecture* definitions should match.

**rpm -V *packagename* *packagename-debuginfo***

This command should produce no output, except possibly modified configuration files of *packagename*, for example.

**rpm -qi *packagename* *packagename-debuginfo***

The *version-release.architecture* should display matching information for Vendor, Build Date, and Build Host. For example, using a CentOS debuginfo RPM for a Red Hat Enterprise Linux RPM package will not work.

If the required build-id is known, the following command can query which RPM contains it:

```
$ repoquery --disablerepo='*' --enablerepo='*-debug*' -qf
/usr/lib/debug/.build-id/ef/dd0b5e69b0742fa5e5bad0771df4d1df2459d1
```

For example, a version of an executable which matches the core file can be installed by:

```
# yum --enablerepo='*-debug*' install $(eu-unstrip -n --core=./core.9814
| sed -e 's#^[\^ ]* \(\.\.\)\([^\@ ]*\)\.*$#/usr/lib/debug/.build-id/\1/\2#p'
-e 's/$/.debug/' )
```

Similar methods are available if the binaries are not packaged into RPMs and stored in yum repositories. It is possible to create local repositories with custom application builds by using **/usr/bin/createrepo**.

## 5.3. GDB

Fundamentally, like most debuggers, GDB manages the execution of compiled code in a very closely controlled environment. This environment makes possible the following fundamental mechanisms necessary to the operation of GDB:

- » Inspect and modify memory within the code being debugged (for example, reading and setting variables).
- » Control the execution state of the code being debugged, principally whether it's running or stopped.

- » Detect the execution of particular sections of code (for example, stop running code when it reaches a specified area of interest to the programmer).
- » Detect access to particular areas of memory (for example, stop running code when it accesses a specified variable).
- » Execute portions of code (from an otherwise stopped program) in a controlled manner.
- » Detect various programmatic asynchronous events such as signals.

The operation of these mechanisms rely mostly on information produced by a compiler. For example, to view the value of a variable, GDB has to know:

- » The location of the variable in memory
- » The nature of the variable

This means that displaying a double-precision floating point value requires a very different process from displaying a string of characters. For something complex like a structure, GDB has to know not only the characteristics of each individual elements in the structure, but the morphology of the structure as well.

GDB requires the following items in order to fully function:

### **Debug Information**

Much of GDB's operations rely on a program's *debug information*. While this information generally comes from compilers, much of it is necessary only while debugging a program, that is, it is not used during the program's normal execution. For this reason, compilers do not always make that information available by default — GCC, for instance, must be explicitly instructed to provide this debugging information with the `-g` flag.

To make full use of GDB's capabilities, it is *highly advisable* to make the debug information available first to GDB. GDB can only be of *very limited* use when run against code with no available debug information.

### **Source Code**

One of the most useful features of GDB (or any other debugger) is the ability to associate events and circumstances in program execution with their corresponding location in source code. This location normally refers to a specific line or series of lines in a source file. This, of course, would require that a program's source code be available to GDB at debug time.

## **5.3.1. Simple GDB**

GDB literally contains dozens of commands. This section describes the most fundamental ones.

### **br (breakpoint)**

The breakpoint command instructs GDB to halt execution upon reaching a specified point in the execution. That point can be specified a number of ways, but the most common are just as the line number in the source file, or the name of a function. Any number of breakpoints can be in effect simultaneously. This is frequently the first command issued after starting GDB.

### **r (run)**

The **run** command starts the execution of the program. If **run** is executed with any arguments, those arguments are passed on to the executable as if the program has been started normally. Users normally issue this command after setting breakpoints.

Before an executable is started, or once the executable stops at, for example, a breakpoint, the state of many aspects of the program can be inspected. The following commands are a few of the more common ways things can be examined.

### **p (print)**

The **print** command displays the value of the argument given, and that argument can be almost anything relevant to the program. Usually, the argument is the name of a variable of any complexity, from a simple single value to a structure. An argument can also be an expression valid in the current language, including the use of program variables and library functions, or functions defined in the program being tested.

### **bt (backtrace)**

The **backtrace** displays the chain of function calls used up until the execution was terminated. This is useful for investigating serious bugs (such as segmentation faults) with elusive causes.

### **l (list)**

When execution is stopped, the **list** command shows the line in the source code corresponding to where the program stopped.

The execution of a stopped program can be resumed in a number of ways. The following are the most common.

### **c (continue)**

The **continue** command restarts the execution of the program, which will continue to execute until it encounters a breakpoint, runs into a specified or emergent condition (for example, an error), or terminates.

### **n (next)**

Like **continue**, the **next** command also restarts execution; however, in addition to the stopping conditions implicit in the **continue** command, **next** will also halt execution at the next sequential line of code in the current source file.

### **s (step)**

Like **next**, the **step** command also halts execution at each sequential line of code in the current source file. However, if execution is currently stopped at a source line containing a *function call*, GDB stops execution after entering the function call (rather than executing it).

### **fini (finish)**

Like the aforementioned commands, the **finish** command resumes executions, but halts when execution returns from a function.

Finally, two essential commands:

### **q (quit)**

This terminates the execution.

### **h (help)**

The **help** command provides access to its extensive internal documentation. The command takes arguments: **help breakpoint** (or **h br**), for example, shows a detailed description of the **breakpoint** command. See the **help** output of each command for more detailed information.

### 5.3.2. Running GDB

This section will describe a basic execution of GDB, using the following simple program:

**hello.c**

```
#include <stdio.h>

char hello[] = { "Hello, World!" };

int
main()
{
    fprintf (stdout, "%s\n", hello);
    return (0);
}
```

The following procedure illustrates the debugging process in its most basic form.

#### Procedure 5.1. Debugging a 'Hello World' Program

1. Compile [hello.c](#) into an executable with the debug flag set, as in:

```
gcc -g -o hello hello.c
```

Ensure that the resulting binary **hello** is in the same directory as **hello.c**.

2. Run **gdb** on the **hello** binary, that is, **gdb hello**.
3. After several introductory comments, **gdb** will display the default GDB prompt:

(gdb)

4. The variable **hello** is global, so it can be seen even before the **main** procedure starts:

```
(gdb) p hello
$1 = "Hello, World!"
(gdb) p hello[0]
$2 = 72 'H'
(gdb) p *hello
$3 = 72 'H'
(gdb)
```

Note that the **print** targets **hello[0]** and **\*hello** require the evaluation of an expression, as does, for example, **\*(hello + 1)**:

```
(gdb) p *(hello + 1)
$4 = 101 'e'
```

5. Next, list the source:

```
(gdb) l
1      #include <stdio.h>
2
3      char hello[] = { "Hello, World!" };
4
5      int
6      main()
7      {
8          fprintf (stdout, "%s\n", hello);
9          return (0);
10     }
```

The **list** reveals that the **fprintf** call is on line 8. Apply a breakpoint on that line and resume the code:

```
(gdb) br 8
Breakpoint 1 at 0x80483ed: file hello.c, line 8.
(gdb) r
Starting program: /home/moller/tinkering/gdb-manual/hello

Breakpoint 1, main () at hello.c:8
8      fprintf (stdout, "%s\n", hello);
```

6. Finally, use the **next** command to step past the **fprintf** call, executing it:

```
(gdb) n
Hello, World!
9      return (0);
```

The following sections describe more complex applications of GDB.

### 5.3.3. Conditional Breakpoints

In many real-world cases, a program may perform its task well during the first few thousand times; it may then start crashing or encountering errors during its eight thousandth iteration of the task. Debugging programs like this can be difficult, as it is hard to imagine a programmer with the patience to issue a **continue** command thousands of times just to get to the iteration that crashed.

Situations like this are common in real life, which is why GDB allows programmers to attach conditions to a breakpoint. For example, consider the following program:

#### simple.c

```
#include <stdio.h>

main()
{
    int i;
```

```

for (i = 0;; i++) {
    fprintf (stdout, "i = %d\n", i);
}
}
```

To set a conditional breakpoint at the GDB prompt:

```
(gdb) br 8 if i == 8936
Breakpoint 1 at 0x80483f5: file iterations.c, line 8.
(gdb) r
```

With this condition, the program execution will eventually stop with the following output:

```

i = 8931
i = 8932
i = 8933
i = 8934
i = 8935

Breakpoint 1, main () at iterations.c:8
8         fprintf (stdout, "i = %d\n", i);
```

Inspect the breakpoint information (using **info br**) to review the breakpoint status:

```
(gdb) info br
Num      Type            Disp Enb Address     What
1        breakpoint      keep y  0x080483f5 in main at iterations.c:8
stop only if i == 8936
breakpoint already hit 1 time
```

### 5.3.4. Forked Execution

Among the more challenging bugs confronting programmers is where one program (the *parent*) makes an independent copy of itself (a *fork*). That fork then creates a *child* process which, in turn, fails. Debugging the parent process may or may not be useful. Often the only way to get to the bug may be by debugging the child process, but this is not always possible.

The **set follow-fork-mode** feature is used to overcome this barrier allowing programmers to follow a child process instead of the parent process.

**set follow-fork-mode parent**

The original process is debugged after a fork. The child process runs unimpeded. This is the default.

**set follow-fork-mode child**

The new process is debugged after a fork. The parent process runs unimpeded.

**show follow-fork-mode**

Display the current debugger response to a fork call.

Use the **set detach-on-fork** command to debug both the parent and the child processes after a fork, or retain debugger control over them both.

**set detach-on-fork on**

The child process (or parent process, depending on the value of **follow-fork-mode**) will be detached and allowed to run independently. This is the default.

**set detach-on-fork off**

Both processes will be held under the control of GDB. One process (child or parent, depending on the value of **follow-fork-mode**) is debugged as usual, while the other is suspended.

**show detach-on-fork**

Show whether **detach-on-fork** mode is on or off.

Consider the following program:

**fork.c**

```
#include <unistd.h>

int main()
{
    pid_t pid;
    const char *name;

    pid = fork();
    if (pid == 0)
    {
        name = "I am the child";
    }
    else
    {
        name = "I am the parent";
    }
    return 0;
}
```

This program, compiled with the command **gcc -g fork.c -o fork -lpthread** and examined under GDB will show:

```
gdb ./fork
[...]
(gdb) break main
Breakpoint 1 at 0x40005dc: file fork.c, line 8.
(gdb) run
[...]
Breakpoint 1, main () at fork.c:8
8  pid = fork();
(gdb) next
Detaching after fork from child process 3840.
9  if (pid == 0)
(gdb) next
15     name = "I am the parent";
```

```
(gdb) next
17  return 0;
(gdb) print name
$1 = 0x400717 "I am the parent"
```

GDB followed the parent process and allowed the child process (process 3840) to continue execution.

The following is the same test using **set follow-fork-mode child**.

```
(gdb) set follow-fork-mode child
(gdb) break main
Breakpoint 1 at 0x4005dc: file fork.c, line 8.
(gdb) run
[...]
Breakpoint 1, main () at fork.c:8
8  pid = fork();
(gdb) next
[New process 3875]
[Thread debugging using libthread_db enabled]
[Switching to Thread 0x7ffff7fd5720 (LWP 3875)]
9  if (pid == 0)
(gdb) next
11      name = "I am the child";
(gdb) next
17  return 0;
(gdb) print name
$2 = 0x400708 "I am the child"
(gdb)
```

GDB switched to the child process here.

This can be permanent by adding the setting to the appropriate **.gdbinit**.

For example, if **set follow-fork-mode ask** is added to **~/.gdbinit**, then ask mode becomes the default mode.

### 5.3.5. Debugging Individual Threads

GDB has the ability to debug individual threads, and to manipulate and examine them independently. This functionality is not enabled by default. To do so use **set non-stop on** and **set target-async on**. These can be added to **.gdbinit**. Once that functionality is turned on, GDB is ready to conduct thread debugging.

For example, the following program creates two threads. These two threads, along with the original thread executing main makes a total of three threads.

#### **three-threads.c**

```
#include <stdio.h>
#include <pthread.h>
#include <unistd.h>

pthread_t thread;

void* thread3 (void* d)
```

```

{
    int count3 = 0;

    while(count3 < 1000){
        sleep(10);
        printf("Thread 3: %d\n", count3++);
    }
    return NULL;
}

void* thread2 (void* d)
{
    int count2 = 0;

    while(count2 < 1000){
        printf("Thread 2: %d\n", count2++);
    }
    return NULL;
}

int main (){
    pthread_create (&thread, NULL, thread2, NULL);
    pthread_create (&thread, NULL, thread3, NULL);

    //Thread 1
    int count1 = 0;

    while(count1 < 1000){
        printf("Thread 1: %d\n", count1++);
    }

    pthread_join(thread,NULL);
    return 0;
}

```

Compile this program in order to examine it under GDB.

```

gcc -g three-threads.c -o three-threads -lpthread
gdb ./three-threads

```

First set breakpoints on all thread functions; `thread1`, `thread2`, and `main`.

```

(gdb) break thread3
Breakpoint 1 at 0x4006c0: file three-threads.c, line 9.
(gdb) break thread2
Breakpoint 2 at 0x40070c: file three-threads.c, line 20.
(gdb) break main
Breakpoint 3 at 0x40074a: file three-threads.c, line 30.

```

Then run the program.

```

(gdb) run
[...]
Breakpoint 3, main () at three-threads.c:30

```

```

30  pthread_create (&thread, NULL, thread2, NULL);
[...]
(gdb) info threads
* 1 Thread 0x7ffff7fd5720 (LWP 4620)  main () at three-threads.c:30
(gdb)

```

Note that the command **info threads** provides a summary of the program's threads and some details about their current state. In this case there is only one thread that has been created so far.

Continue execution some more.

```

(gdb) next
[New Thread 0x7ffff7fd3710 (LWP 4687)]
31  pthread_create (&thread, NULL, thread3, NULL);
(gdb)
Breakpoint 2, thread2 (d=0x0) at three-threads.c:20
20  int count2 = 0;
next
[New Thread 0x7ffff75d2710 (LWP 4688)]
34  int count1 = 0;
(gdb)
Breakpoint 1, thread3 (d=0x0) at three-threads.c:9
9   int count3 = 0;
info threads
  3 Thread 0x7ffff75d2710 (LWP 4688)  thread3 (d=0x0) at three-
threads.c:9
  2 Thread 0x7ffff7fd3710 (LWP 4687)  thread2 (d=0x0) at three-
threads.c:20
* 1 Thread 0x7ffff7fd5720 (LWP 4620)  main () at three-threads.c:34

```

Here, two more threads are created. The star indicates the thread currently under focus. Also, the newly created threads have hit the breakpoint set for them in their initialization functions. Namely, `thread2()` and `thread3()`.

To begin real thread debugging, use the **thread <thread number>** command to switch the focus to another thread.

```

(gdb) thread 2
[Switching to thread 2 (Thread 0x7ffff7fd3710 (LWP 4687))]#0  thread2
(d=0x0)
    at three-threads.c:20
20  int count2 = 0;
(gdb) list
15  return NULL;
16 }
17
18 void* thread2 (void* d)
19 {
20  int count2 = 0;
21
22  while(count2 < 1000){
23      printf("Thread 2: %d\n", count2++);
24  }

```

Thread 2 stopped at line 20 in its function thread2().

```
(gdb) next
22  while(count2 < 1000){
(gdb) print count2
$1 = 0
(gdb) next
23  printf("Thread 2: %d\n", count2++);
(gdb) next
Thread 2: 0
22  while(count2 < 1000){
(gdb) next
23  printf("Thread 2: %d\n", count2++);
(gdb) print count2
$2 = 1
(gdb) info threads
  3 Thread 0x7ffff75d2710 (LWP 4688)  thread3 (d=0x0) at three-
threads.c:9
* 2 Thread 0x7ffff7fd3710 (LWP 4687)  thread2 (d=0x0) at three-
threads.c:23
  1 Thread 0x7ffff7fd5720 (LWP 4620)  main () at three-threads.c:34
(gdb)
```

Above, a few lines of thread2 printed the counter count2 and left thread 2 at line 23 as is seen by the output of 'info threads'.

Now thread3.

```
(gdb) thread 3
[Switching to thread 3 (Thread 0x7ffff75d2710 (LWP 4688))]#0  thread3
(d=0x0)
    at three-threads.c:9
9  int count3 = 0;
(gdb) list
4
5 pthread_t thread;
6
7 void* thread3 (void* d)
8 {
9  int count3 = 0;
10
11 while(count3 < 1000){
12     sleep(10);
13     printf("Thread 3: %d\n", count3++);
(gdb)
```

Thread three is a little different in that it has a sleep statement and executes slowly. Think of it as a representation of an uninteresting IO thread. Because this thread is uninteresting, continue its execution uninterrupted, using the **continue**.

```
(gdb) continue &
(gdb) Thread 3: 0
Thread 3: 1
Thread 3: 2
Thread 3: 3
```

Take note of the & at the end of the **continue**. This allows the GDB prompt to return so other commands can be executed. Using the **interrupt**, execution can be stopped should thread 3 become interesting again.

```
(gdb) interrupt
[Thread 0xfffff75d2710 (LWP 4688)] #3 stopped.
0x000000343f4a6a6d in nanosleep () at
./sysdeps/unix/syscall-template.S:82
82 T_PSEUDO (SYSCALL_SYMBOL, SYSCALL_NAME, SYSCALL_NARGS)
```

It is also possible to go back to the original main thread and examine it some more.

```
(gdb) thread 1
[Switching to thread 1 (Thread 0xfffff7fd5720 (LWP 4620))]#0  main ()
  at three-threads.c:34
34  int count1 = 0;
(gdb) next
36  while(count1 < 1000){
(gdb) next
37      printf("Thread 1: %d\n", count1++);
(gdb) next
Thread 1: 0
36  while(count1 < 1000){
(gdb) next
37      printf("Thread 1: %d\n", count1++);
(gdb) next
Thread 1: 1
36  while(count1 < 1000){
(gdb) next
37      printf("Thread 1: %d\n", count1++);
(gdb) next
Thread 1: 2
36  while(count1 < 1000){
(gdb) print count1
$3 = 3
(gdb) info threads
  3 Thread 0xfffff75d2710 (LWP 4688)  0x000000343f4a6a6d in nanosleep ()
    at ./sysdeps/unix/syscall-template.S:82
  2 Thread 0xfffff7fd3710 (LWP 4687)  thread2 (d=0x0) at three-
threads.c:23
* 1 Thread 0xfffff7fd5720 (LWP 4620)  main () at three-threads.c:36
(gdb)
```

As can be seen from the output of **info threads**, the other threads are where they were left, unaffected by the debugging of thread 1.

### 5.3.6. Alternative User Interfaces for GDB

GDB uses the command line as its default interface. However, it also has an API called *machine interface* (MI). MI allows IDE developers to create other user interfaces to GDB.

Some examples of these interfaces are:

**Eclipse (CDT)**

A graphical debugger interface integrated with the Eclipse development environment. More information can be found at the [Eclipse website](#).

### Nemiver

A graphical debugger interface which is well suited to the GNOME Desktop Environment. More information can be found at the [Nemiver website](#)

### Emacs

A GDB interface which is integrated with the emacs. More information can be found at the [Emacs website](#)

## 5.3.7. GDB Documentation

For more detailed information about GDB, see the GDB manual:

<http://sources.redhat.com/gdb/current/onlinedocs/gdb.html>

Also, the commands `info gdb` and `man gdb` will provide more concise information that is up to date with the installed version of gdb.

## 5.4. Variable Tracking at Assignments

*Variable Tracking at Assignments* (VTA) is a new infrastructure included in GCC used to improve variable tracking during optimizations. This allows GCC to produce more precise, meaningful, and useful debugging information for GDB, SystemTap, and other debugging tools.

When GCC compiles code with optimizations enabled, variables are renamed, moved around, or even removed altogether. As such, optimized compiling can cause a debugger to report that some variables have been <optimized out>. With VTA enabled, optimized code is internally annotated to ensure that optimization passes transparently keep track of each variable's value, regardless of whether the variable is moved or removed. The effect of this is more parameter and variable values available, even for the optimized (`gcc -O2 -g` built) code. It also displays the <optimized out> message less.

VTA's benefits are more pronounced when debugging applications with inlined functions. Without VTA, optimization could completely remove some arguments of an inlined function, preventing the debugger from inspecting its value. With VTA, optimization will still happen, and appropriate debugging information will be generated for any missing arguments.

VTA is enabled by default when compiling code with optimizations and debugging information enabled (that is, `gcc -O -g` or, more commonly, `gcc -O2 -g`). To disable VTA during such builds, add the `-fno-var-tracking-assignments`. In addition, the VTA infrastructure includes the new `gcc` option `-fcompare-debug`. This option tests code compiled by GCC with debug information and without debug information: the test passes if the two binaries are identical. This test ensures that executable code is not affected by any debugging options, which further ensures that there are no hidden bugs in the debug code. Note that `-fcompare-debug` adds significant cost in compilation time. See `man gcc` for details about this option.

For more information about the infrastructure and development of VTA, see *A Plan to Fix Local Variable Debug Information in GCC*, available at the following link:

[http://gcc.gnu.org/wiki/Var\\_Tracking\\_Assignments](http://gcc.gnu.org/wiki/Var_Tracking_Assignments)

A slide deck version of this whitepaper is also available at <http://people.redhat.com/aoliva/papers/vta/slides.pdf>.

## 5.5. Python Pretty-Printers

The GDB command `print` outputs comprehensive debugging information for a target application. GDB aims to provide as much debugging data as it can to users; however, this means that for highly complex programs the amount of data can become very cryptic.

In addition, GDB does not provide any tools that help decipher GDB `print` output. GDB does not even empower users to easily create tools that can help decipher program data. This makes the practice of reading and understanding debugging data quite arcane, particularly for large, complex projects.

For most developers, the only way to customize GDB `print` output (and make it more meaningful) is to revise and recompile GDB. However, very few developers can actually do this. Further, this practice will not scale well, particularly if the developer must also debug other programs that are heterogeneous and contain equally complex debugging data.

To address this, the Red Hat Enterprise Linux 6 version of GDB is now compatible with Python *pretty-printers*. This allows the retrieval of more meaningful debugging data by leaving the introspection, printing, and formatting logic to a *third-party* Python script.

Compatibility with Python pretty-printers gives you the chance to truly customize GDB output as you see fit. This makes GDB a more viable debugging solution to a wider range of projects, since you now have the flexibility to *adapt* GDB output as required, and with greater ease. Further, developers with intimate knowledge of a project and a specific programming language are best qualified in deciding what kind of output is meaningful, allowing them to improve the usefulness of that output.

The Python pretty-printers implementation allows users to automatically inspect, format, and print program data according to specification. These specifications are written as rules implemented via Python scripts. This offers the following benefits:

### Safe

To pass program data to a set of registered Python pretty-printers, the GDB development team added *hooks* to the GDB printing code. These hooks were implemented with safety in mind: the built-in GDB printing code is still intact, allowing it to serve as a default fallback printing logic. As such, if no specialized printers are available, GDB will still print debugging data the way it always did. This ensures that GDB is backwards-compatible; users who do not require pretty-printers can still continue using GDB.

### Highly Customizable

This new "Python-scripted" approach allows users to distill as much knowledge as required into specific printers. As such, a project can have an entire library of printer scripts that parses program data in a unique manner specific to its user's requirements. There is no limit to the number of printers a user can build for a specific project; what's more, being able to customize debugging data script by script offers users an easier way to re-use and re-purpose printer scripts — or even a whole library of them.

### Easy to Learn

The best part about this approach is its lower barrier to entry. Python scripting is comparatively easy to learn and has a large library of free documentation available online. In addition, most programmers already have basic to intermediate experience in Python scripting, or in scripting in general.

Here is a small example of a pretty printer. Consider the following C++ program:

```
enum Fruits {Orange, Apple, Banana};

class Fruit
{
    int fruit;

public:
    Fruit (int f)
    {
        fruit = f;
    }
};

int main()
{
    Fruit myFruit(Apple);
    return 0;           // line 17
}
```

This is compiled with the command `g++ -g fruit.cc -o fruit`. Now, examine this program with GDB.

```
gdb ./fruit
[...]
(gdb) break 17
Breakpoint 1 at 0x400056d: file fruit.cc, line 17.
(gdb) run

Breakpoint 1, main () at fruit.cc:17
17  return 0;           // line 17
(gdb) print myFruit
$1 = {fruit = 1}
```

The output of `{fruit = 1}` is correct because that is the internal representation of 'fruit' in the data structure 'Fruit'. However, this is not easily read by humans as it is difficult to tell which fruit the integer 1 represents.

To solve this problem, write the following pretty printer:

```
fruit.py

class FruitPrinter:
    def __init__(self, val):
        self.val = val

    def to_string (self):
        fruit = self.val['fruit']

        if (fruit == 0):
            name = "Orange"
        elif (fruit == 1):
            name = "Apple"
        elif (fruit == 2):
            name = "Banana"
```

```

        else:
            name = "unknown"
            return "Our fruit is " + name

def lookup_type (val):
    if str(val.type) == 'Fruit':
        return FruitPrinter(val)
    return None

gdb.pretty_printers.append (lookup_type)

```

Examine this printer from the bottom up.

The line `gdb.pretty_printers.append (lookup_type)` adds the function `lookup_type` to GDB's list of printer lookup functions.

The function `lookup_type` is responsible for examining the type of object to be printed, and returning an appropriate pretty printer. The object is passed by GDB in the parameter `val`. `val.type` is an attribute which represents the type of the pretty printer.

`FruitPrinter` is where the actual work is done. More specifically in the `to_string` function of that Class. In this function, the integer `fruit` is retrieved using the python dictionary syntax `self.val['fruit']`. Then the name is determined using that value. The string returned by this function is the string that will be printed to the user.

After creating `fruit.py`, it must then be loaded into GDB with the following command:

```
(gdb) python execfile("fruit.py")
```

The *GDB and Python Pretty-Printers* whitepaper provides more details on this feature. This whitepaper also includes details and examples on how to write your own Python pretty-printer as well as how to import it into GDB. See the following link for more information:

<http://sourceware.org/gdb/onlinedocs/gdb/Pretty-Printing.html>

## 5.6. Debugging C/C++ Applications with Eclipse

The Eclipse C/C++ development tools have excellent integration with the GNU Debugger (GDB). These Eclipse plug-ins take advantage of the latest features available in GDB.

Starting a debugging session for an application is similar to launching the application through either the context menu's **Debug As → C/C++ Application**, or using the **Run** menu. The context menu can be accessed in one of three ways:

- » Clicking the right mouse button with the cursor in the editor.
- » On the application binary.
- » On the project containing the binary of interest.

If more than one binary can be launched, a dialog will be presented to choose which one.

After the session has started, a prompt will appear to switch to the Debug perspective, which contains the following collection of views related to debugging.

### Control View

The Control View is known as the Debug view and has buttons for stepping over and into

code selections. It also allows for thread process suspension.

### Source Code Editor View

The Source Code Editor View reflects which source code lines correspond to the position of the debugger in the execution. By pressing the **Instruction Stepping Mode** button in the Debug view toolbar, it is possible to control the execution of the application by assembly instruction instead of by source code line.

### Console View

The Console View displays the input and output that is available.

Finally, variable data and other information can be found in the corresponding views in the Debug perspective.

For further details, see the **Concepts → Debug, Getting Started → Debugging Projects**, and **Tasks → Running and Debugging Projects** sections of the *C/C++ Development User Guide* in the Help Contents.

# Chapter 6. Profiling

Developers profile programs to focus attention on the areas of the program that have the largest impact on performance. The types of data collected include what section of the program consumes the most processor time, and where memory is allocated. Profiling collects data from the actual program execution. Thus, the quality of the data collect is influenced by the actual tasks being performed by the program. The tasks performed during profiling should be representative of actual use; this ensures that problems arising from realistic use of the program are addressed during development.

Red Hat Enterprise Linux 6 includes a number of different tools (Valgrind, OProfile, **perf**, and SystemTap) to collect profiling data. Each tool is suitable for performing specific types of profile runs, as described in the following sections.

## 6.1. Valgrind

**Valgrind** is an instrumentation framework for building dynamic analysis tools that can be used to profile applications in detail. **Valgrind** tools are generally used to automatically detect many memory management and threading problems. The **Valgrind** suite also includes tools that allow the building of new profiling tools as required.

**Valgrind** provides instrumentation for user-space binaries to check for errors, such as the use of uninitialized memory, improper allocation/freeing of memory, and improper arguments for systemcalls. Its profiling tools can be used by normal users on most binaries; however, compared to other profilers, **Valgrind** profile runs are significantly slower. To profile a binary, **Valgrind** rewrites its executable and instruments the rewritten binary. **Valgrind**'s tools are most useful for looking for memory-related issues in user-space programs; it is not suitable for debugging time-specific issues or kernel-space instrumentation/debugging.

Previously, **Valgrind** did not support IBM System z architecture. However, as of 6.1, this support has been added, meaning **Valgrind** now supports all hardware architectures that are supported by Red Hat Enterprise Linux 6.x.

### 6.1.1. Valgrind Tools

The **Valgrind** suite is composed of the following tools:

#### **memcheck**

This tool detects memory management problems in programs by checking all reads from and writes to memory and intercepting all system calls to **malloc**, **new**, **free**, and **delete**. **memcheck** is perhaps the most used **Valgrind** tool, as memory management problems can be difficult to detect using other means. Such problems often remain undetected for long periods, eventually causing crashes that are difficult to diagnose.

#### **cachegrind**

**cachegrind** is a cache profiler that accurately pinpoints sources of cache misses in code by performing a detailed simulation of the I1, D1 and L2 caches in the CPU. It shows the number of cache misses, memory references, and instructions accruing to each line of source code; **cachegrind** also provides per-function, per-module, and whole-program summaries, and can even show counts for each individual machine instructions.

#### **callgrind**

Like **cachegrind**, **callgrind** can model cache behavior. However, the main purpose of **callgrind** is to record callgraphs data for the executed code.

### **massif**

**massif** is a heap profiler; it measures how much heap memory a program uses, providing information on heap blocks, heap administration overheads, and stack sizes. Heap profilers are useful in finding ways to reduce heap memory usage. On systems that use virtual memory, programs with optimized heap memory usage are less likely to run out of memory, and may be faster as they require less paging.

### **helgrind**

In programs that use the POSIX pthreads threading primitives, **helgrind** detects synchronization errors. Such errors are:

- » Misuses of the POSIX pthreads API
- » Potential deadlocks arising from lock ordering problems
- » Data races (that is, accessing memory without adequate locking)

**Valgrind** also allows you to develop your own profiling tools. In line with this, **Valgrind** includes the **lackey** tool, which is a sample that can be used as a template for generating your own tools.

## 6.1.2. Using Valgrind

The **valgrind** package and its dependencies install all the necessary tools for performing a **Valgrind** profile run. To profile a program with **Valgrind**, use:

```
valgrind --tool=toolname program
```

See [Section 6.1.1, “Valgrind Tools”](#) for a list of arguments for **toolname**. In addition to the suite of **Valgrind** tools, **none** is also a valid argument for **toolname**; this argument allows you to run a program under **Valgrind** without performing any profiling. This is useful for debugging or benchmarking **Valgrind** itself.

You can also instruct **Valgrind** to send all of its information to a specific file. To do so, use the option **--log-file=filename**. For example, to check the memory usage of the executable file **hello** and send profile information to **output**, use:

```
valgrind --tool=memcheck --log-file=output hello
```

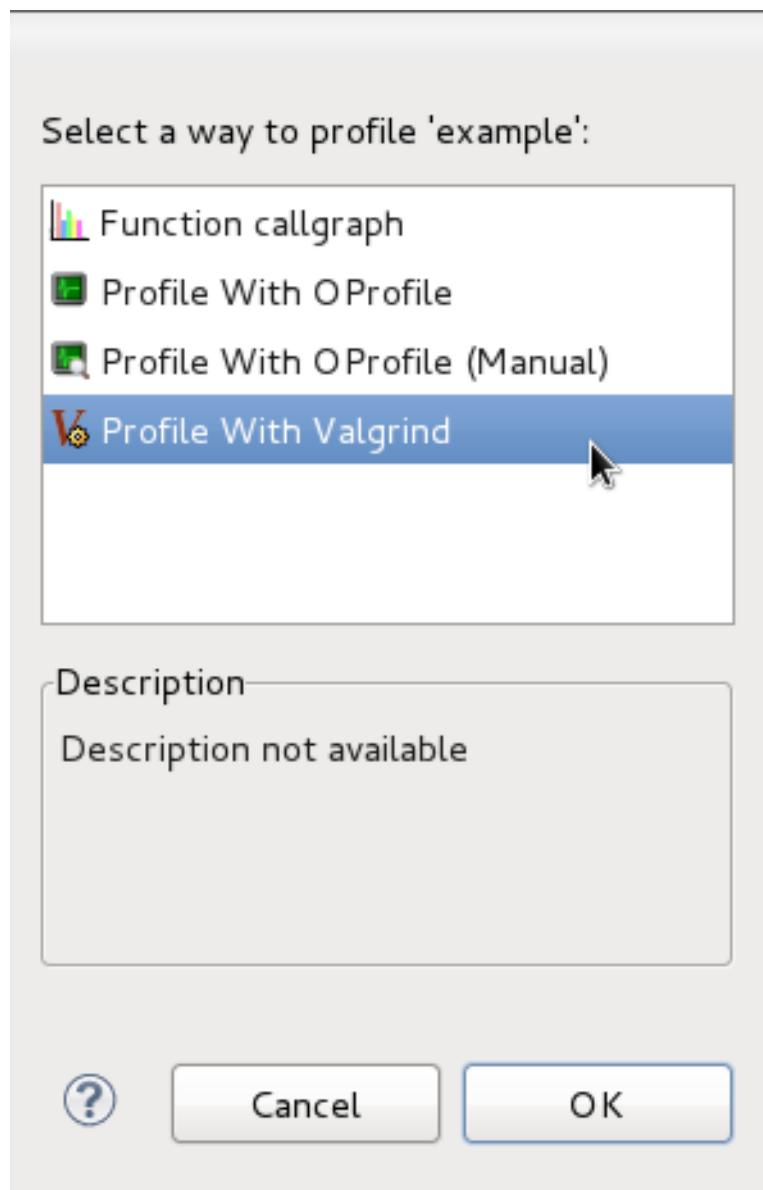

See [Section 6.1.4, “Valgrind Documentation”](#) for more information on **Valgrind**, along with other available documentation on the **Valgrind** suite of tools.

## 6.1.3. Valgrind Plug-in for Eclipse

The **Valgrind** plug-in for Eclipse integrates several **Valgrind** tools into Eclipse. This allows Eclipse users to seamlessly include profiling capabilities into their workflow. At present, the **Valgrind** plug-in for Eclipse supports three **Valgrind** tools:

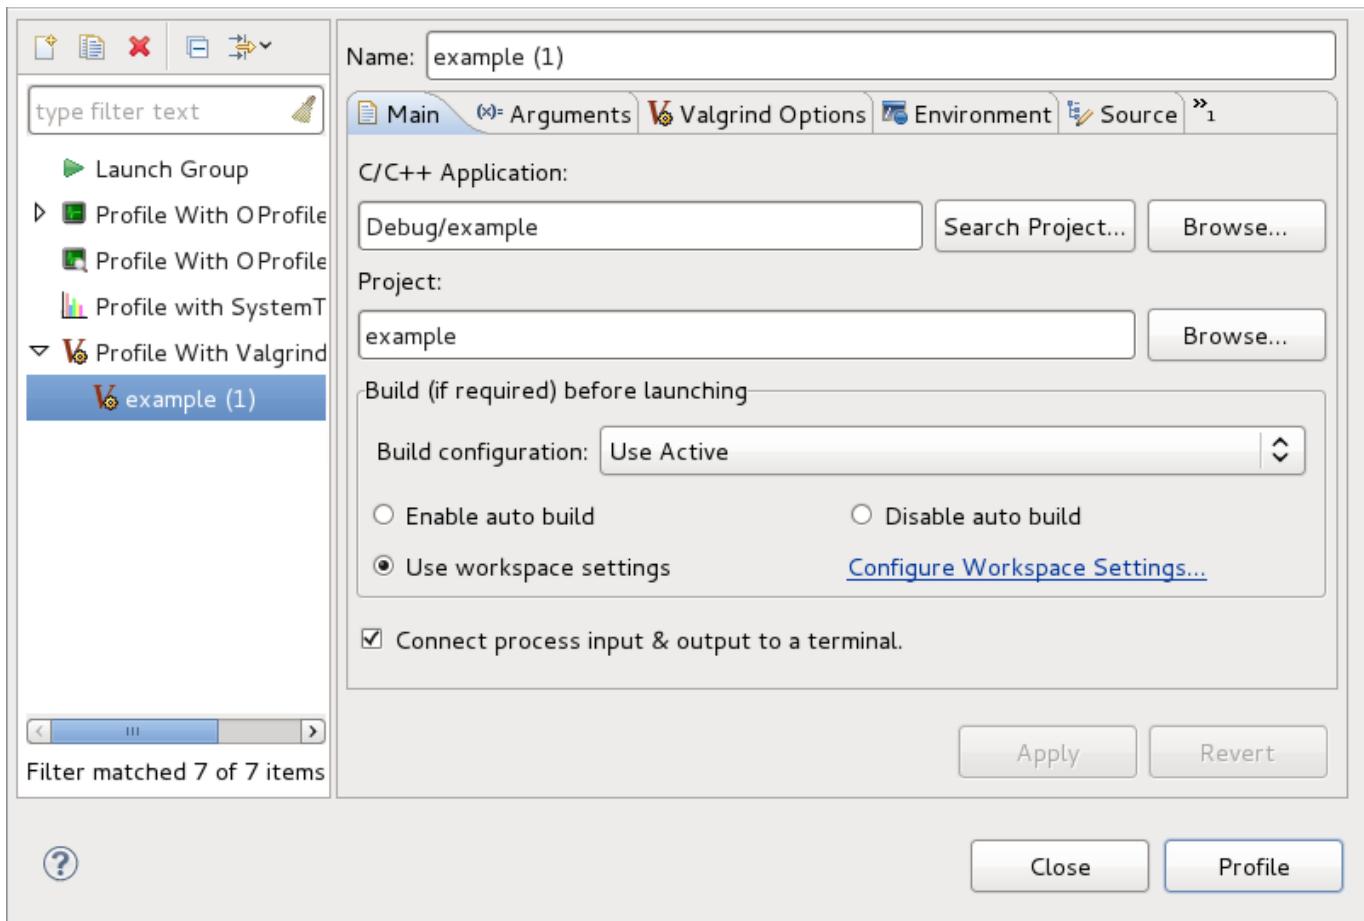

- » **Memcheck**
- » **Massif**
- » **Cachegrind**

To launch a **Valgrind** profile run, navigate to **Run > Profile**. This will open the **Profile As** dialog, from which you can select a tool for a profile run.

**Figure 6.1. Profile As**

To configure each tool for a profile run, navigate to **Run > Profile Configuration**. This will open the **Profile Configuration** menu.

**Figure 6.2. Profile Configuration**

The **Valgrind** plug-in for Eclipse is provided by the **eclipse-valgrind** package. For more information about this plug-in, see *Valgrind Integration User Guide* in the Eclipse **Help Contents**.

#### 6.1.4. Valgrind Documentation

For more extensive information on **Valgrind**, see **man valgrind**. Red Hat Enterprise Linux 6 also provides a comprehensive *Valgrind Documentation* book, available as PDF and HTML in:

- » **file:///usr/share/doc/valgrind-version/valgrind\_manual.pdf**
- » **file:///usr/share/doc/valgrind-version/html/index.html**

The *Valgrind Integration User Guide* in the Eclipse **Help Contents** also provides detailed information on the setup and usage of the **Valgrind** plug-in for Eclipse. This guide is provided by the **eclipse-valgrind** package.

## 6.2. OProfile

OProfile is a system-wide Linux profiler, capable of running at low overhead. It consists of a kernel driver and a daemon for collecting raw sample data, along with a suite of tools for parsing that data into meaningful information. OProfile is generally used by developers to determine which sections of code consume the most amount of CPU time, and why.

During a profile run, OProfile uses the processor's performance monitoring hardware. **Valgrind** rewrites the binary of an application, and in turn instruments it. OProfile, on the other hand, profiles a running application as-is. It sets up the performance monitoring hardware to take a sample every x

number of events (for example, cache misses or branch instructions). Each sample also contains information on where it occurred in the program.

OProfile's profiling methods consume less resources than **Valgrind**. However, OProfile requires root privileges. OProfile is useful for finding "hot-spots" in code, and looking for their causes (for example, poor cache performance, branch mispredictions).

Using OProfile involves starting the OProfile daemon (**oprofiled**), running the program to be profiled, collecting the system profile data, and parsing it into a more understandable format. OProfile provides several tools for every step of this process.

### 6.2.1. OProfile Tools

The most useful OProfile commands include the following:

#### **opcontrol**

This tool is used to start/stop the OProfile daemon and configure a profile session.

#### **opreport**

The **opreport** command outputs binary image summaries, or per-symbol data, from OProfile profiling sessions.

#### **opannotate**

The **opannotate** command outputs annotated source and/or assembly from the profile data of an OProfile session.

#### **oparchive**

The **oparchive** command generates a directory populated with executable, debug, and OProfile sample files. This directory can be moved to another machine (via **tar**), where it can be analyzed offline.

#### **opgprof**

Like **opreport**, the **opgprof** command outputs profile data for a given binary image from an OProfile session. The output of **opgprof** is in **gprof** format.

For a complete list of OProfile commands, see **man oprofile**. For detailed information on each OProfile command, see its corresponding **man** page. See [Section 6.2.4, “OProfile Documentation”](#) for other available documentation on OProfile.

### 6.2.2. Using OProfile

The **oprofile** package and its dependencies install all the necessary utilities for executing OProfile. To instruct OProfile to profile all the applications running on the system and to group the samples for the shared libraries with the application using the library, run the following command:

```
# opcontrol --no-vmlinu --separate=library --start
```

You can also start the OProfile daemon without collecting system data. To do so, use the option **--start-daemon**. The **--stop** option halts data collection, while **--shutdown** terminates the OProfile daemon.

Use **opreport**, **opannotate**, or **opgprof** to display the collected profiling data. By default, the data collected by the OProfile daemon is stored in **/var/lib/oprofile/samples/**.

## OProfile conflict with Performance Counters for Linux (PCL) tools

Both OProfile and Performance Counters for Linux (PCL) use the same hardware Performance Monitoring Unit (PMU). If the PCL or the NMI watchdog timer are using the hardware PMU, a message like the following occurs when starting OProfile:

```
# opcontrol --start
Using default event: CPU_CLK_UNHALTED:100000:0:1:1
Error: counter 0 not available nmi_watchdog using this resource ? Try:
opcontrol --deinit
echo 0 > /proc/sys/kernel/nmi_watchdog
```

Stop any **perf** commands running on the system, then turn off the NMI watchdog and reload the OProfile kernel driver with the following commands:

```
# opcontrol --deinit
# echo 0 > /proc/sys/kernel/nmi_watchdog
```

### 6.2.3. OProfile Plug-in For Eclipse

The **OProfile** suite of tools provide powerful call profiling capabilities; as a plug-in, these capabilities are well ported into the Eclipse user interface. The **OProfile** Plug-in provides the following benefits:

#### Targeted Profiling

The **OProfile** Plug-in will allow Eclipse users to profile a specific binary, include related shared libraries/kernel modules, and even exclude binaries. This produces very targeted, detailed usage results on each binary, function, and symbol, down to individual line numbers in the source code.

#### User Interface Fully Integrated into CDT

The plug-in displays enriched **OProfile** results through Eclipse, just like any other plug-in. Double-clicking on a source line in the results brings users directly to the corresponding line in the Eclipse editor. This allows users to build, profile, and edit code through a single interface, making profiling a convenient experience for Eclipse users. In addition, profile runs are launched and configured the same way as C/C++ applications within Eclipse.

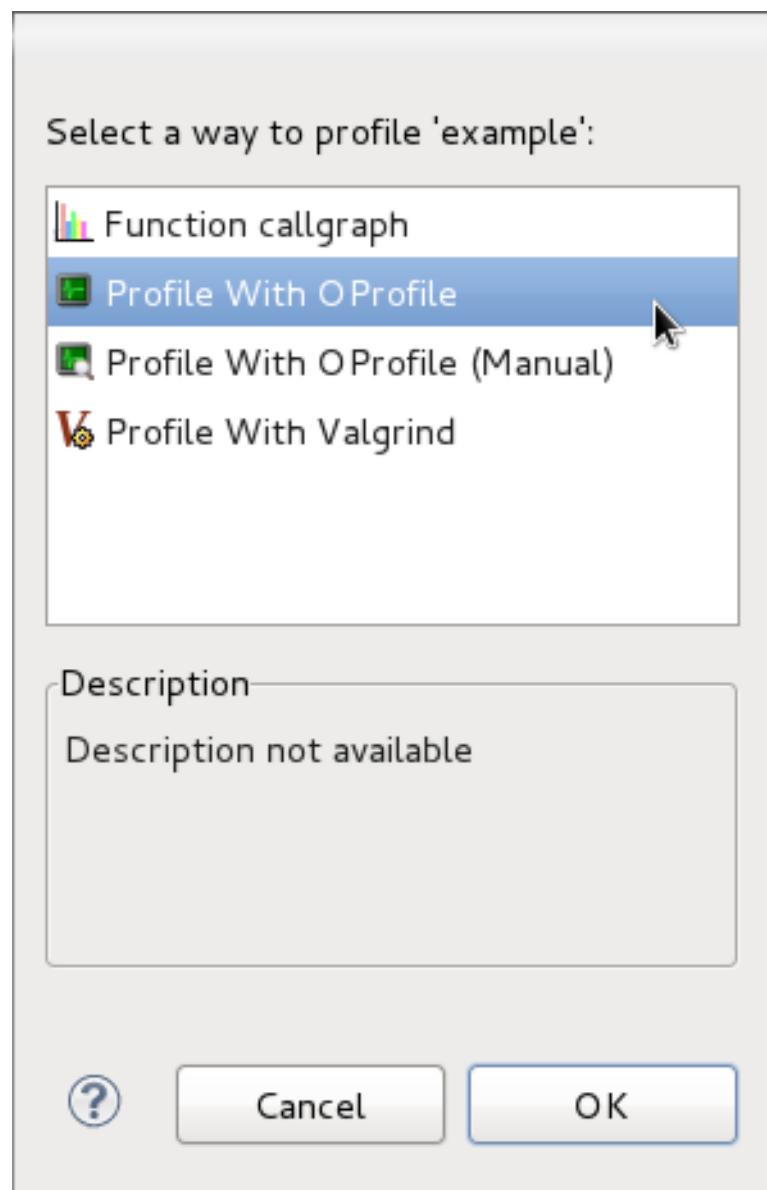

#### Fully Customizable Profiling Options

The Eclipse interface allows users to configure their profile run using all options available in the **OProfile** command line utility. The plug-in supports event configuration based on processor debugging registers (that is, counters), as well as interrupt-based profiling for kernels or processors that do not support hardware counters.

#### Ease of Use

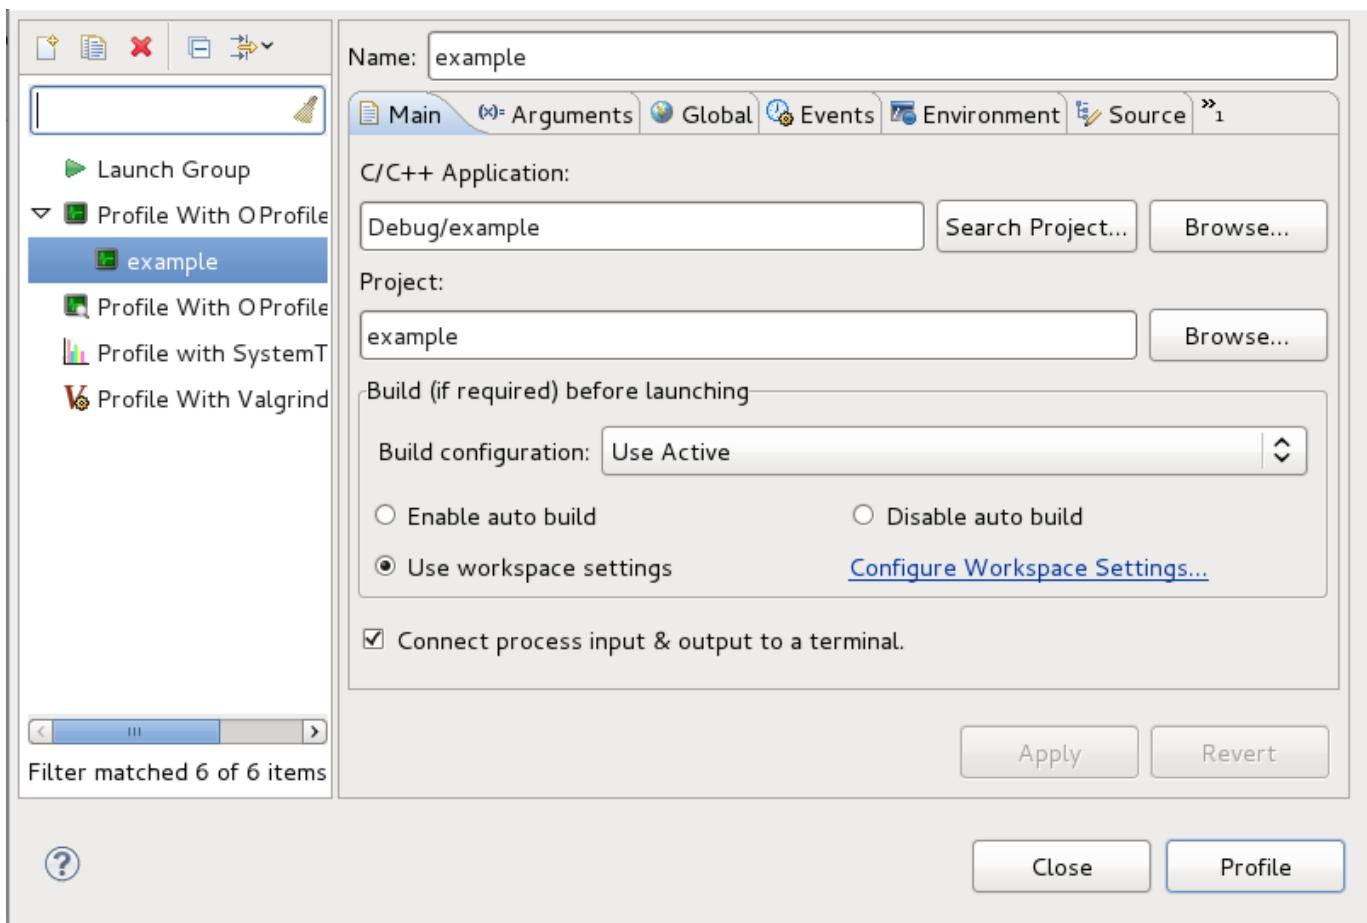

The **OProfile** Plug-in provides generally useful defaults for all options, usable for a majority of profiling runs. In addition, it also features a "one-click profile" that executes a profile run using these defaults. Users can profile applications from start to finish, or select specific areas of code through a manual control dialog.

To launch a **Valgrind** profile run, navigate to **Run > Profile**. This will open the **Profile As** dialog, from which you can select a tool for a profile run.

**Figure 6.3. Profile As**

To configure each tool for a profile run, navigate to **Run > Profile Configuration**. This will open the **Profile Configuration** menu.

**Figure 6.4. Profile Configuration**

The OProfile plug-in for Eclipse is provided by the **eclipse-oprofile** package. For more information about this plug-in, see *OProfile Integration User Guide* in the Eclipse **Help Contents** (also provided by **eclipse-profile**).

#### 6.2.4. OProfile Documentation

For a more extensive information on OProfile, see **man oprofile**. Red Hat Enterprise Linux 6 also provides two comprehensive guides to OProfile in  
**file:///usr/share/doc/oprofile-version/**:

##### OProfile Manual

A comprehensive manual with detailed instructions on the setup and use of OProfile is found at **file:///usr/share/doc/oprofile-version/oprofile.html**

##### OProfile Internals

Documentation on the internal workings of OProfile, useful for programmers interested in contributing to the OProfile upstream, can be found at  
**file:///usr/share/doc/oprofile-version/internals.html**

The *OProfile Integration User Guide* in the Eclipse **Help Contents** also provides detailed information on the setup and usage of the OProfile plug-in for Eclipse. This guide is provided by the **eclipse-oprofile** package.

## 6.3. SystemTap

SystemTap is a useful instrumentation platform for probing running processes and kernel activity on the Linux system. To execute a probe:

1. Write *SystemTap scripts* that specify which system events (for example, virtual file system reads, packet transmissions) should trigger specified actions (for example, print, parse, or otherwise manipulate data).
2. SystemTap translates the script into a C program, which it compiles into a kernel module.
3. SystemTap loads the kernel module to perform the actual probe.

SystemTap scripts are useful for monitoring system operation and diagnosing system issues with minimal intrusion into the normal operation of the system. You can quickly instrument running system test hypotheses without having to recompile and re-install instrumented code. To compile a SystemTap script that probes *kernel-space*, SystemTap uses information from three different *kernel information packages*:

- » **`kernel-variant-devel-version`**
- » **`kernel-variant-debuginfo-version`**
- » **`kernel-debuginfo-common-arch-version`**

### Note

The kernel information package in Red Hat Enterprise Linux 6 is now named **`kernel-debuginfo-common-arch-version`**. It was originally **`kernel-debuginfo-common-version`** in Red Hat Enterprise Linux 5.

These kernel information packages must match the kernel to be probed. In addition, to compile SystemTap scripts for multiple kernels, the kernel information packages of each kernel must also be installed.

An important new feature has been added as of Red Hat Enterprise Linux 6.1: the **`--remote`** option. This allows users to build the SystemTap module locally, and then execute it remotely via SSH. The syntax to use this is **`--remote [USER@]HOSTNAME`**; set the execution target to the specified SSH host, optionally using a different username. This option may be repeated to target multiple execution targets. Passes 1-4 are completed locally as normal to build the script, and then pass 5 copies the module to the target and runs it.

The following sections describe other new SystemTap features available in the Red Hat Enterprise Linux 6 release.

#### 6.3.1. SystemTap Compile Server

SystemTap in Red Hat Enterprise Linux 6 supports a *compile server and client* deployment. With this setup, the kernel information packages of *all* client systems in the network are installed on just one compile server host (or a few). When a client system attempts to compile a kernel module from a SystemTap script, it remotely accesses the kernel information it requires from the centralized compile server host.

A properly configured and maintained SystemTap compile server host offers the following benefits:

- » The system administrator can verify the integrity of kernel information packages before making the packages available to users.

- » The identity of a compile server can be authenticated using the *Secure Socket Layer* (SSL). SSL provides an encrypted network connection that prevents eavesdropping or tampering during transmission.
- » Individual users can run their own servers and authorize them for their own use as trusted.
- » System administrators can authorize one or more servers on the network as trusted for use by all users.
- » A server that has not been explicitly authorized is ignored, preventing any server impersonations and similar attacks.

### 6.3.2. SystemTap Support for Unprivileged Users

For security purposes, users in an enterprise setting are rarely given privileged (that is, root or **sudo**) access to their own machines. In addition, full SystemTap functionality should also be restricted to privileged users, as this can provide the ability to completely take control of a system.

SystemTap in Red Hat Enterprise Linux 6 features a new option to the SystemTap client: **--unprivileged**. This option allows an unprivileged user to run **stap**. Of course, several restrictions apply to unprivileged users that attempt to run **stap**.

#### Note

An unprivileged user is a member of the group **stapusr** but is not a member of the group **stapdev** (and is not root).

Before loading any kernel modules created by unprivileged users, SystemTap verifies the integrity of the module using standard digital (cryptographic) signing techniques. Each time the **--unprivileged** option is used, the server checks the script against the constraints imposed for unprivileged users. If the checks are successful, the server compiles the script and signs the resulting module using a self-generated certificate. When the client attempts to load the module, **staprund** first verifies the signature of the module by checking it against a database of trusted signing certificates maintained and authorized by root.

Once a signed kernel module is successfully verified, **staprund** is assured that:

- » The module was created using a trusted systemtap server implementation.
- » The module was compiled using the **--unprivileged** option.
- » The module meets the restrictions required for use by an unprivileged user.
- » The module has not been tampered with since it was created.

### 6.3.3. SSL and Certificate Management

SystemTap in Red Hat Enterprise Linux 6 implements authentication and security via certificates and public/private key pairs. It is the responsibility of the system administrator to add the credentials (that is, certificates) of compile servers to a database of trusted servers. SystemTap uses this database to verify the identity of a compile server that the client attempts to access. Likewise, SystemTap also uses this method to verify kernel modules created by compile servers using the **--unprivileged** option.

#### 6.3.3.1. Authorizing Compile Servers for Connection

The first time a compile server is started on a server host, the compile server automatically generates a certificate. This certificate verifies the compile server's identity during SSL authentication and module signing.

In order for clients to access the compile server (whether on the same server host or from a client machine), the system administrator must add the compile server's certificate to a database of trusted servers. Each client host intending to use compile servers maintains such a database. This allows individual users to customize their database of trusted servers, which can include a list of compile servers authorized for their own use only.

### 6.3.3.2. Authorizing Compile Servers for Module Signing (for Unprivileged Users)

Unprivileged users can only load signed, authorized SystemTap kernel modules. For modules to be recognized as such, they have to be created by a compile server whose certificate appears in a database of trusted signers; this database must be maintained on each host where the module will be loaded.

### 6.3.3.3. Automatic Authorization

Servers started using the **stap-server** initscript are automatically authorized to receive connections from all clients on the same host.

Servers started by other means are automatically authorized to receive connections from clients on the same host run by the user who started the server. This was implemented with convenience in mind; users are automatically authorized to connect to a server they started themselves, provided that both client and server are running on the same host.

Whenever root starts a compile server, *all* clients running on the same host automatically recognize the server as authorized. However, Red Hat advises that you refrain from doing so.

Similarly, a compile server initiated through **stap-server** is automatically authorized as a trusted signer on the host in which it runs. If the compile server was initiated through other means, it is not automatically authorized as such.

### 6.3.4. SystemTap Documentation

For more detailed information about SystemTap, see the following books (also provided by Red Hat):

- » *SystemTap Beginner's Guide*
- » *SystemTap Tapset Reference*
- » *SystemTap Language Reference* (documentation supplied by IBM)

The *SystemTap Beginner's Guide* and *SystemTap Tapset Reference* are also available locally when you install the **systemtap** package:

- » **file:///usr/share/doc/systemtap-version/SystemTap\_Beginners\_Guide/index.html**
- » **file:///usr/share/doc/systemtap-version/SystemTap\_Beginners\_Guide.pdf**
- » **file:///usr/share/doc/systemtap-version/tapsets/index.html**
- » **file:///usr/share/doc/systemtap-version/tapsets.pdf**

[Section 6.3.1, “SystemTap Compile Server”](#), [Section 6.3.2, “SystemTap Support for Unprivileged Users”](#), and [Section 6.3.3, “SSL and Certificate Management”](#) are all excerpts from the *SystemTap*

*Support for Unprivileged Users and Server Client Deployment* whitepaper. This whitepaper also provides more details on each feature, along with a case study to help illustrate their application in a real-world environment.

## 6.4. Performance Counters for Linux (PCL) Tools and perf

*Performance Counters for Linux (PCL)* is a new kernel-based subsystem that provides a framework for collecting and analyzing performance data. These events will vary based on the performance monitoring hardware and the software configuration of the system. Red Hat Enterprise Linux 6 includes this kernel subsystem to collect data and the user-space tool **perf** to analyze the collected performance data.

The PCL subsystem can be used to measure hardware events, including retired instructions and processor clock cycles. It can also measure software events, including major page faults and context switches. For example, PCL counters can compute the *Instructions Per Clock* (IPC) from a process's counts of instructions retired and processor clock cycles. A low IPC ratio indicates the code makes poor use of the CPU. Other hardware events can also be used to diagnose poor CPU performance.

Performance counters can also be configured to record samples. The relative frequency of samples can be used to identify which regions of code have the greatest impact on performance.

### 6.4.1. Perf Tool Commands

Useful **perf** commands include the following:

#### **perf stat**

This **perf** command provides overall statistics for common performance events, including instructions executed and clock cycles consumed. Options allow selection of events other than the default measurement events.

#### **perf record**

This **perf** command records performance data into a file which can be later analyzed using **perf report**.

#### **perf report**

This **perf** command reads the performance data from a file and analyzes the recorded data.

#### **perf list**

This **perf** command lists the events available on a particular machine. These events will vary based on the performance monitoring hardware and the software configuration of the system.

Use **perf help** to obtain a complete list of **perf** commands. To retrieve **man** page information on each **perf** command, use **perf help command**.

### 6.4.2. Using Perf

Using the basic PCL infrastructure for collecting statistics or samples of program execution is relatively straightforward. This section provides simple examples of overall statistics and sampling.

To collect statistics on **make** and its children, use the following command:

```
# perf stat -- make all
```

The **perf** command collects a number of different hardware and software counters. It then prints the following information:

Performance counter stats for 'make all':

244011.782059	task-clock-msecs	#	0.925 CPUs
53328	context-switches	#	0.000 M/sec
515	CPU-migrations	#	0.000 M/sec
1843121	page-faults	#	0.008 M/sec
789702529782	cycles	#	3236.330 M/sec
1050912611378	instructions	#	1.331 IPC
275538938708	branches	#	1129.203 M/sec
2888756216	branch-misses	#	1.048 %
4343060367	cache-references	#	17.799 M/sec
428257037	cache-misses	#	1.755 M/sec
263.779192511 seconds time elapsed			

The **perf** tool can also record samples. For example, to record data on the **make** command and its children, use:

```
# perf record -- make all
```

This prints out the file in which the samples are stored, along with the number of samples collected:

```
[ perf record: Woken up 42 times to write data ]
[ perf record: Captured and wrote 9.753 MB perf.data (~426109 samples) ]
```

As of Red Hat Enterprise Linux 6.4, a new functionality to the **{}** group syntax has been added that allows the creation of event groups based on the way they are specified on the command line.

The current **--group** or **-g** options remain the same; if it is specified for record, stat, or top command, all the specified events become members of a single group with the first event as a group leader.

The new **{}** group syntax allows the creation of a group like:

```
# perf record -e '{cycles, faults}' ls
```

The above results in a single event group containing *cycles* and *faults* events, with the *cycles* event as the group leader.

All groups are created with regards to threads and CPUs. As such, recording an event group within two threads on a server with four CPUs will create eight separate groups.

It is possible to use a standard event modifier for a group. This spans over all events in the group and updates each event modifier settings.

```
# perf record -r '{faults:k, cache-references}:p'
```

The above command results in the **:kp** modifier being used for *faults*, and the **:p** modifier being used for the *cache-references* event.

## Performance Counters for Linux (PCL) Tools conflict with OProfile

Both OProfile and Performance Counters for Linux (PCL) use the same hardware Performance Monitoring Unit (PMU). If OProfile is currently running while attempting to use the PCL **perf** command, an error message like the following occurs when starting OProfile:

```
Error: open_counter returned with 16 (Device or resource busy).
/bin/dmesg may provide additional information.
```

```
Fatal: Not all events could be opened.
```

To use the **perf** command, first shut down OProfile:

```
# opcontrol --deinit
```

You can then analyze **perf.data** to determine the relative frequency of samples. The report output includes the command, object, and function for the samples. Use **perf report** to output an analysis of **perf.data**. For example, the following command produces a report of the executable that consumes the most time:

```
# perf report --sort=comm
```

The resulting output:

```
# Samples: 1083783860000
#
# Overhead          Command
# ..... .
#
 48.19%      xsltproc
 44.48%      pdfxmltex
  6.01%      make
  0.95%      perl
  0.17%      kernel-doc
  0.05%      xmllint
  0.05%      cc1
  0.03%      cp
  0.01%      xmlto
  0.01%      sh
  0.01%      docproc
  0.01%      ld
  0.01%      gcc
  0.00%      rm
  0.00%      sed
  0.00%      git-diff-files
  0.00%      bash
  0.00%      git-diff-index
```

The column on the left shows the relative frequency of the samples. This output shows that **make** spends most of this time in **xsltproc** and the **pdfxmltex**. To reduce the time for the **make** to complete, focus on **xsltproc** and **pdfxmltex**. To list the functions executed by **xsltproc**, run:

```
# perf report -n --comm=xsltproc
```

This generates:

```
comm: xsltproc
# Samples: 472520675377
#
# Overhead  Samples          Shared Object  Symbol
# ..... . . . . . . . . . . . . . . .
#
    45.54%215179861044  libxml2.so.2.7.6      [ . ]
xmlXPathCmpNodesExt
    11.63%54959620202  libxml2.so.2.7.6      [ . ]

    2.19%10340901937  libxml2.so.2.7.6      [ . ]
valuePush__internal_alias
```

## 6.5. ftrace

The **ftrace** framework provides users with several tracing capabilities, accessible through an interface much simpler than SystemTap's. This framework uses a set of virtual files in the **debugfs** file system; these files enable specific tracers. The **ftrace** function tracer outputs each function called in the kernel in real time; other tracers within the **ftrace** framework can also be used to analyze wakeup latency, task switches, kernel events, and the like.

You can also add new tracers for **ftrace**, making it a flexible solution for analyzing kernel events. The **ftrace** framework is useful for debugging or analyzing latencies and performance issues that take place outside of user-space. Unlike other profilers documented in this guide, **ftrace** is a built-in feature of the kernel.

### 6.5.1. Using ftrace

The Red Hat Enterprise Linux 6 kernels have been configured with the **CONFIG\_FTRACE=y** option. This option provides the interfaces required by **ftrace**. To use **ftrace**, mount the **debugfs** file system as follows:

```
mount -t debugfs nodev /sys/kernel/debug
```

All the **ftrace** utilities are located in **/sys/kernel/debug/tracing/**. View the **/sys/kernel/debug/tracing/available\_tracers** file to find out what tracers are available for your kernel:

```
cat /sys/kernel/debug/tracing/available_tracers
```

```
power wakeup irqsoff function sysprof sched_switch initcall nop
```

To use a specific tracer, write it to `/sys/kernel/debug/tracing/current_tracer`. For example, `wakeup` traces and records the maximum time it takes for the highest-priority task to be scheduled after the task wakes up. To use it:

```
echo wakeup > /sys/kernel/debug/tracing/current_tracer
```

To start or stop tracing, write to `/sys/kernel/debug/tracing/tracing_on`, as in:

```
echo 1 > /sys/kernel/debug/tracing/tracing_on (enables tracing)
```

```
echo 0 > /sys/kernel/debug/tracing/tracing_on (disables tracing)
```

The results of the trace can be viewed from the following files:

#### **`/sys/kernel/debug/tracing/trace`**

This file contains human-readable trace output.

#### **`/sys/kernel/debug/tracing/trace_pipe`**

This file contains the same output as `/sys/kernel/debug/tracing/trace`, but is meant to be piped into a command. Unlike `/sys/kernel/debug/tracing/trace`, reading from this file consumes its output.

### **6.5.2. ftrace Documentation**

The **ftrace** framework is fully documented in the following files:

- » *ftrace - Function Tracer: file:///usr/share/doc/kernel-doc-version/Documentation/trace/ftrace.txt*
- » *function tracer guts: file:///usr/share/doc/kernel-doc-version/Documentation/trace/ftrace-design.txt*

# Chapter 7. Red Hat Developer Toolset

## 7.1. What is Red Hat Developer Toolset?

Red Hat Developer Toolset is a Red Hat offering for developers on the Red Hat Enterprise Linux platform, and provides a complete set of development and performance analysis tools that can be installed and used on multiple versions of Red Hat Enterprise Linux. Executables built with the Red Hat Developer Toolset toolchain can then also be deployed and run on multiple versions of Red Hat Enterprise Linux.

Red Hat Developer Toolset does not replace the default system tools and libraries provided with Red Hat Enterprise Linux 6 when installed on this platform. Instead, a parallel set of developer tools provides an alternative, newer version of those tools for optional use by developers. Applications and libraries provided by Red Hat Developer Toolset do not replace the Red Hat Enterprise Linux system versions, nor are they used in preference to the system versions. The default compiler and debugger, for example, remain those provided by the base Red Hat Enterprise Linux system.

Developers can pick and choose at any time which version of the tool they would like to use by using the `scl` utility. For details on how to install the product and invoke the executables, see the [Red Hat Developer Toolset 3.0 User Guide](#).

## 7.2. What Does Red Hat Developer Toolset Offer?

In comparison with Red Hat Enterprise Linux 6, Red Hat Developer Toolset provides more recent versions of the **Eclipse** development environment, **GNU Compiler Collection (GCC)**, **GNU Debugger (GDB)**, and other development and performance analysis tools as listed in [Table 7.1, “Red Hat Developer Toolset Components”](#). These updated tools allow developers to develop applications while using experimental C++14 language features, the latest compiler optimizations, parallel programming with OpenMP 4.0, and improved debugging support.

**Table 7.1. Red Hat Developer Toolset Components**

Name	Version	Description
Eclipse	4.4	An integrated development environment with a graphical user interface. [a]
GCC	4.9.1	A portable compiler suite with support for C, C++, and Fortran.
binutils	2.24	A collection of binary tools and other utilities to inspect and manipulate object files and binaries.
elfutils	0.159	A collection of binary tools and other utilities to inspect and manipulate ELF files.
dwz	0.11	A tool to optimize DWARF debugging information contained in ELF shared libraries and ELF executables for size.
GDB	7.8	A command line debugger for programs written in C, C++, and Fortran.
ltrace	0.7.91	A debugging tool to display calls to dynamic libraries that a program makes. It can also monitor system calls executed by programs.
strace	4.8	A debugging tool to monitor system calls that a program uses and signals it receives.
memstomp	0.1.5	A debugging tool to identify calls to library functions with overlapping memory regions that are not allowed by various standards.

Name	Version	Description
SystemTap	2.5	A tracing and probing tool to monitor the activities of the entire system without the need to instrument, recompile, install, and reboot.
Valgrind	3.9.0	An instrumentation framework and a number of tools to profile applications in order to detect memory errors, identify memory management problems, and report any use of improper arguments in system calls.
OProfile	0.9.9	A system-wide profiler that uses the performance monitoring hardware on the processor to retrieve information about the kernel and executables on the system.
Dyninst	8.2	A library for instrumenting and working with user-space executables during their execution.

[a] If you intend to develop applications for Red Hat JBoss Middleware or require support for OpenShift Tools, it is recommended that you use [Red Hat JBoss Developer Studio](#).

## 7.3. Platform Compatibility

Red Hat Developer Toolset 3.0 is available for Red Hat Enterprise Linux 6 and 7 for 64-bit Intel and AMD architectures. [Figure 7.1, “Red Hat Developer Toolset 3.0 Compatibility Matrix”](#) illustrates the support for binaries built with Red Hat Developer Toolset on a certain version of Red Hat Enterprise Linux when those binaries are run on various other versions of this system.

For ABI compatibility information, see the [ABI Compatibility](#) section of the *Red Hat Developer Toolset 3.0 User Guide*.

		<i>“Run on”</i>			
		6.4 EUS	6.5	6.6	7.0
<i>“Built with”</i>	6.4 EUS	✓	✓	✓	✓
	6.5	✗	✓	✓	✓
	6.6	✗	✗	✓	✓
	7.0	✗	✗	✗	✓
	✗ Unsupported	✓ Supported			

**Figure 7.1. Red Hat Developer Toolset 3.0 Compatibility Matrix**

## 7.4. Additional Resources

For more information about Red Hat Developer Toolset, see the resources listed below.

- [Red Hat Developer Toolset 3.0 Release Notes](#) — The *Release Notes* for Red Hat Developer Toolset 3.0 provide important information available at the time of its release. Read this book to learn about system requirements or known problems of the product.

- » [Red Hat Developer Toolset 3.0 User Guide](#) — The *User Guide* for Red Hat Developer Toolset 3.0 provides an overview of the product, explains how to invoke and use the Red Hat Developer Toolset versions of the tools, and links to resources with more in-depth information. Read this book to learn how to obtain, install, and use Red Hat Developer Toolset on your system, or for a detailed list of changes in this product.

## Chapter 8. Red Hat Software Collections

### 8.1. What is Red Hat Software Collections?

For certain applications, more recent versions of some software components are often needed in order to use their latest features. Red Hat Software Collections is a Red Hat offering that provides a set of dynamic programming languages, database servers, and related packages that are either more recent than their equivalent versions included in the base Red Hat Enterprise Linux system, or are available for this system for the first time.

Dynamic languages, database servers, and other tools distributed with Red Hat Software Collections do *not* replace the default system tools provided with Red Hat Enterprise Linux 6, nor are they used in preference to these tools. The default versions of **Perl** and **PostgreSQL**, for example, remain those provided by the base Red Hat Enterprise Linux system. Users can pick and choose at any time which version of the tool they would like to run by using the **scl** utility.

With the notable exception of **Node.js**, all Red Hat Software Collections components are fully supported under Red Hat Enterprise Linux Subscription Level Agreements, are functionally complete, and are intended for production use.

Red Hat Developer Toolset is now a part of Red Hat Software Collections, included as a separate Software Collection. For more information about Red Hat Developer Toolset, see the [Red Hat Developer Toolset Release Notes](#) and the [Red Hat Developer Toolset User Guide](#).

### 8.2. What Does Red Hat Software Collections Offer?

Red Hat Software Collections 1.2 provides recent versions of the tools listed in [Table 8.1, “6 Components”](#).

**Table 8.1. 6 Components**

Component	Software Collection	Description
<b>Red Hat Developer Toolset 3.0</b>	<i>devtoolset-3</i>	Red Hat Developer Toolset is designed for developers on the Red Hat Enterprise Linux platform. It provides current versions of the <b>GNU Compiler Collection</b> , <b>GNU Debugger</b> , <b>Eclipse</b> development platform, and other development, debugging, and performance monitoring tools. For a complete list of components, see the <a href="#">Red Hat Developer Toolset Components</a> table in the <a href="#">Red Hat Developer Toolset User Guide</a> .
<b>Perl 5.16.3</b>	<i>perl516</i>	A release of Perl with a number of additional utilities, scripts, and <i>database connectors for MySQL and PostgreSQL</i> . This version provides a large number of new features and enhancements, including new debugging options, improved Unicode support, and better performance. Also, it adds <b>perl-DateTime</b> and <b>mod_perl</b> , which is supported only with the <i>httpd24</i> Software Collection package.

Component	Software Collection	Description
<b>PHP 5.4.16</b>	<i>php54</i>	A release of PHP with <b>PEAR 1.9.4</b> and a number of additional extensions. PHP 5.4 provides a number of <i>language and interface improvements</i> . The <b>APC</b> , <b>memcache</b> , and <b>Zend OPcache</b> extensions are also included.
<b>PHP 5.5.6</b>	<i>php55</i>	A release of PHP with <i>enhanced language features</i> including better exception handling, generators, and <b>Zend OPcache</b> . The <b>memcache</b> and <b>mongodb</b> extensions are also included.
<b>Python 2.7.5</b>	<i>python27</i>	A release of Python 2.7 with a number of additional utilities. This Python version provides various new features and enhancements, including a new ordered dictionary type, faster I/O operations, and improved forward compatibility with Python 3. The <i>python27</i> Software Collections contains the <i>Python 2.7.5 interpreter</i> , a set of extension libraries useful for programming web applications and <b>mod_wsgi</b> (only supported with the <i>httpd24</i> Software Collection), MySQL and PostgreSQL database connectors, and <b>numpy</b> and <b>scipy</b> .
<b>Python 3.3.2</b>	<i>python33</i>	A release of Python 3 with a number of additional utilities. This Software Collection gives developers on Red Hat Enterprise Linux access to Python 3 and allows them to benefit from various advantages and new features of this version. The <i>python33</i> Software Collection contains <i>Python 3.3.2 interpreter</i> , a set of extension libraries useful for programming web applications and <b>mod_wsgi</b> (only supported with the <i>httpd24</i> Software Collection), PostgreSQL database connector, and <b>numpy</b> and <b>scipy</b> .
<b>Ruby 1.9.3 [a]</b>	<i>ruby193</i>	A release of Ruby 1.9.3 and <b>Ruby on Rails 3.2.8</b> with a <i>large collection of Ruby gems</i> . This Software Collection gives developers on Red Hat Enterprise Linux access to Ruby 1.9, which provides a number of new features and enhancements, including improved Unicode support, enhanced threading, faster load times, and <b>mod_passenger</b> , which is supported only with the <i>httpd24</i> Software Collection package.
<b>Ruby 2.0.0</b>	<i>ruby200</i>	A release of Ruby 2.0.0. This version provides substantial performance and reliability improvements and includes a number of new features and improved debugging capabilities, while maintaining source level backward compatibility with Ruby 1.9.3.
<b>Ruby on Rails 4.0.2 [a]</b>	<i>ror40</i>	A release of <b>Ruby on Rails 4.0</b> , a web application development framework written in the Ruby language. This version provides a number of new features and improvements and adds live streaming for persistent connections. This Software Collection is supported together with the <i>ruby200</i> collection.

Component	Software Collection	Description
<b>MariaDB 5.5.37</b>	<i>mariadb55</i>	A release of MariaDB, <i>an alternative to MySQL</i> for users of Red Hat Enterprise Linux. MySQL is binary compatible with MariaDB and can be replaced with it without any data conversions. This version adds the PAM authentication plugin to MariaDB.
<b>MongoDB 2.4.9 [b]</b>	<i>mongodb24</i>	A release of MongoDB, a cross-platform <i>document-oriented database system classified as a NoSQL database</i> . This Software Collection includes the <i>mongo-java-driver</i> package.
<b>MySQL 5.5.37</b>	<i>mysql55</i>	A release of MySQL, which provides a number of new features and enhancements, including improved performance.
<b>PostgreSQL 9.2.8</b>	<i>postgresql92</i>	A release of PostgreSQL, which provides a number of new features and enhancements, including <i>cascading replication, native JSON support, improved scalability, and better performance</i> .
<b>Node.js 0.10 [b] [c] [d] nodejs010</b>		A release of Node.js with <b>npm 1.3.24</b> . This Software Collection gives users of Red Hat Enterprise Linux access to this programming platform.
<b>nginx 1.6.1</b>	<i>nginx16</i>	A release of nginx, a web and proxy server with a focus on high concurrency, performance and low memory usage. This version introduces a number of new features, including various <i>SSL improvements</i> , support for <i>SPDY 3.1, cache revalidation with conditional requests, and authentication request module</i> .
<b>Apache httpd 2.4.6</b>	<i>httpd24</i>	A release of the Apache HTTP Server ( <i>httpd</i> ), including a high performance <i>event-based processing model, enhanced SSL module and FastCGI support</i> . The <b>mod_auth_kerb</b> module is also included.
<b>Thermostat 1.0.4</b>	<i>thermostat1</i>	A release of Thermostat, a monitoring and instrumentation tool for the <i>OpenJDK HotSpot JVM</i> , with support for monitoring <i>multiple JVM instances</i> . This Software Collection depends on the <i>mongodb24</i> component.
<b>Git 1.9.4</b>	<i>git19</i>	A release of Git, a <i>distributed revision control system</i> with a peer-to-peer architecture. As opposed to centralized version control systems with a client-server model, Git ensures that each working copy of a Git repository is its exact copy with complete revision history.
<b>DevAssistant 0.9.1</b>	<i>devassist09</i>	A release of DevAssistant, a tool designed to assist developers with <i>creating and setting up basic projects</i> in various programming languages, installing dependencies, setting up a development environment, and working with source control. DevAssistant supports the C, C++, Java, and Python programming languages but it is able to support working with any other language, framework, or tool due to its modular architecture.

Component	Software Collection	Description
Maven 3.0.5	maven30	<p>A release of Maven, a <i>software project management and comprehension tool</i> used primarily for Java projects. Based on the concept of a project object model (POM), Maven can manage a project's build, reporting, and documentation from a central piece of information.</p> <p>[a] A part of this Software Collection requires a JavaScript engine. The v8314 Software Collection included in 6 provides the V8 JavaScript engine and is supported only as the Software Collection's dependency.</p> <p>[b] This Software Collection also requires <b>v8314</b>. The v8314 Software Collection included in 6 provides the V8 JavaScript engine and is supported only as the Software Collection's dependency.</p> <p>[c] In 6, <b>Node.js</b> is included as a Technology Preview. For more information about Red Hat Technology Previews, see <a href="https://access.redhat.com/support/offering/techpreview/">https://access.redhat.com/support/offering/techreview/</a>.</p>

## 8.3. Which Platforms Are Supported?

Red Hat Software Collections 1.2 is available for all supported releases of Red Hat Enterprise Linux 6 on AMD64 and Intel 64 architectures.

## 8.4. How to Use Red Hat Software Collections?

To run an executable from a particular Software Collection, type the following command at a shell prompt:

```
scl enable software_collection... 'command...'
```

Replace *software\_collection* with a space-separated list of Software Collections you want to use and *command* with the command you want to run. For example, to execute a Perl program stored in a file named **hello.pl** with the Perl interpreter from the perl516 Software Collection, type:

```
~]$ scl enable perl516 'perl hello.pl'
Hello, World!
```

To start a new shell session with executables from a selected Software Collection in preference to their Red Hat Enterprise Linux equivalents, type the following at a shell prompt:

```
scl enable software_collection... bash
```

Replace *software\_collection* with a space-separated list of Software Collections you want to use. For example, to start a new shell session with the *python27* and *postgresql92* Software Collections as default, type:

```
~]$ scl enable python27 postgresql92 bash
```

The list of Software Collections that are enabled in the current session is stored in the **\$X\_SCLS** environment variable, for instance:

```
~]$ echo $X_SCLS
python27 postgresql92
```

You can execute any command using the `scl` utility, causing it to be run with the executables from a selected Software Collection in preference to their possible Red Hat Enterprise Linux system equivalents. See [Section 4.7, “Software Collections and scl-utils”](#) for more information on how to install and use this command line utility on your system.

For a complete list of Software Collections that are distributed with Red Hat Software Collections, see [Table 8.1, “6 Components”](#). For detailed instructions on how to use these Software Collections, see the *Red Hat Software Collections 1.1 Release Notes*.

## 8.5. How to Deploy Applications That Use Red Hat Software Collections?

In general, you can use one of the following two approaches to deploy an application that depends on a component from Red Hat Software Collections in production:

- ▶ install all required Software Collections and packages manually and then deploy your application, or
- ▶ create a new Software Collection for your application and specify all required Software Collections and other packages as dependencies.

For more information on how to manually install individual Red Hat Software Collections components, see the [Red Hat Software Collections 1.2 Release Notes](#). For a detailed explanation of how to create a custom Software Collection, read the *Red Hat Developer Toolset Software Collections Guide*.

## 8.6. Additional Resources

- ▶ [Red Hat Software Collections 1.2 Release Notes](#) — The *Release Notes* for Red Hat Software Collections 1.2 provides important information available at the time of its release. Read this book if you want to learn about system requirements or known problems of Red Hat Software Collections.
- ▶ [Red Hat Software Collections 1.2 Packaging Guide](#) — The *Packaging Guide* for Red Hat Software Collections 1.2 provides instructions on how to build custom Software Collections.

## Chapter 9. Documentation Tools

Red Hat Enterprise Linux 6 offers the **Doxygen** tool for generating documentation from source code and for writing standalone documentation.

### 9.1. Doxygen

Doxygen is a documentation tool that creates reference material both online in HTML and offline in Latex. It does this from a set of documented source files which makes it easy to keep the documentation consistent and correct with the source code.

#### 9.1.1. Doxygen Supported Output and Languages

Doxygen has support for output in:

- » RTF (MS Word)
- » PostScript
- » Hyperlinked PDF
- » Compressed HTML
- » Unix man pages

Doxygen supports the following programming languages:

- » C
- » C++
- » C#
- » Objective -C
- » IDL
- » Java
- » VHDL
- » PHP
- » Python
- » Fortran
- » D

#### 9.1.2. Getting Started

Doxygen uses a configuration file to determine its settings, therefore it is paramount that this be created correctly. Each project requires its own configuration file. The most painless way to create the configuration file is with the command **doxygen -g config-file**. This creates a template configuration file that can be easily edited. The variable *config-file* is the name of the configuration file.

If it is committed from the command line it is called Doxyfile by default. Another useful option while creating the configuration file is the use of a minus sign (-) as the file name. This is useful for scripting as it will cause Doxygen to attempt to read the configuration file from standard input (`stdin`).

The configuration file consists of a number of variables and tags, similar to a simple Makefile. For example:

```
TAGNAME = VALUE1 VALUE2 . . .
```

For the most part these can be left alone but should it be required to edit them see the [configuration page](#) of the Doxygen documentation website for an extensive explanation of all the tags available. There is also a GUI interface called **doxywizard**. If this is the preferred method of editing then documentation for this function can be found on the [Doxywizard usage page](#) of the Doxygen documentation website.

There are eight tags that are useful to become familiar with.

## INPUT

For small projects consisting mainly of C or C++ source and header files it is not required to change anything. However, if the project is large and consists of a source directory or tree, then assign the root directory or directories to the INPUT tag.

## FILE\_PATTERNS

File patterns (for example, `*.cpp` or `*.h`) can be added to this tag allowing only files that match one of the patterns to be parsed.

## RECURSIVE

Setting this to **yes** will allow recursive parsing of a source tree.

## EXCLUDE and EXCLUDE\_PATTERNS

These are used to further fine-tune the files that are parsed by adding file patterns to avoid. For example, to omit all **test** directories from a source tree, use `EXCLUDE_PATTERNS = */test/*`.

## EXTRACT\_ALL

When this is set to **yes**, doxygen will pretend that everything in the source files is documented to give an idea of how a fully documented project would look. However, warnings regarding undocumented members will not be generated in this mode; set it back to **no** when finished to correct this.

## SOURCE\_BROWSER and INLINE\_SOURCES

By setting the **SOURCE\_BROWSER** tag to **yes** doxygen will generate a cross-reference to analyze a piece of software's definition in its source files with the documentation existing about it. These sources can also be included in the documentation by setting **INLINE\_SOURCES** to **yes**.

### 9.1.3. Running Doxygen

Running **doxygen config-file** creates **html**, **rtf**, **latex**, **xml**, and / or **man** directories in whichever directory doxygen is started in, containing the documentation for the corresponding filetype.

## HTML OUTPUT

This documentation can be viewed with a HTML browser that supports cascading style sheets (CSS), as well as DHTML and Javascript for some sections. Point the browser (for example, Mozilla, Safari, Konqueror, or Internet Explorer 6) to the **index.html** in the **html** directory.

## LaTeX OUTPUT

Doxygen writes a **Makefile** into the **latex** directory in order to make it easy to first compile the Latex documentation. To do this, use a recent teTeX distribution. What is contained in this directory depends on whether the **USE\_PDFLATEX** is set to **no**. Where this is true, typing **make** while in the **latex** directory generates **refman.dvi**. This can then be viewed with **xpdf** or converted to **refman.ps** by typing **make ps**. Note that this requires **dvisps**.

There are a number of commands that may be useful. The command **make ps\_2on1** prints two pages on one physical page. It is also possible to convert to a PDF if a ghostscript interpreter is installed by using the command **make pdf**. Another valid command is **make pdf\_2on1**. When doing this set **PDF\_HYPERLINKS** and **USE\_PDFLATEX** tags to **yes** as this will cause **Makefile** will only contain a target to build **refman.pdf** directly.

## RTF OUTPUT

This file is designed to import into Microsoft Word by combining the RTF output into a single file: **refman.rtf**. Some information is encoded using fields but this can be shown by selecting all (**CTRL+A** or Edit -> select all) and then right-click and select the **toggle fields** option from the drop down menu.

## XML OUTPUT

The output into the **xml** directory consists of a number of files, each compound gathered by doxygen, as well as an **index.xml**. An XSLT script, **combine.xslt**, is also created that is used to combine all the XML files into a single file. Along with this, two XML schema files are created, **index.xsd** for the index file, and **compound.xsd** for the compound files, which describe the possible elements, their attributes, and how they are structured.

## MAN PAGE OUTPUT

The documentation from the **man** directory can be viewed with the **man** program after ensuring the **manpath** has the correct man directory in the man path. Be aware that due to limitations with the man page format, information such as diagrams, cross-references and formulas will be lost.

### 9.1.4. Documenting the Sources

There are three main steps to document the sources.

1. First, ensure that **EXTRACT\_ALL** is set to **no** so warnings are correctly generated and documentation is built properly. This allows doxygen to create documentation for documented members, files, classes and namespaces.
2. There are two ways this documentation can be created:

#### A *special* documentation block

This comment block, containing additional marking so Doxygen knows it is part of the documentation, is in either C or C++. It consists of a brief description, or a detailed description. Both of these are optional. What is not optional, however, is the *in body* description. This then links together all the comment blocks found in the body of the method or function.

## Note

While more than one brief or detailed description is allowed, this is not recommended as the order is not specified.

The following will detail the ways in which a comment block can be marked as a detailed description:

- » C-style comment block, starting with two asterisks (\*) in the JavaDoc style.

```
/***
 * ... documentation ...
 */
```

- » C-style comment block using the Qt style, consisting of an exclamation mark (!) instead of an extra asterisk.

```
/*!
 * ... documentation ...
 */
```

- » The beginning asterisks on the documentation lines can be left out in both cases if that is preferred.
- » A blank beginning and end line in C++ also acceptable, with either three forward slashes or two forward slashes and an exclamation mark.

```
///
/// ... documentation
///
```

or

```
///
//! ... documentation ...
//!
```

- » Alternatively, in order to make the comment blocks more visible a line of asterisks or forward slashes can be used.

```
///////////
/// ... documentation ...
///////////
```

or

```
***** 
* ... documentation ...
***** /**
```

Note that the two forwards slashes at the end of the normal comment block start a special comment block.

There are three ways to add a brief description to documentation.

- To add a brief description use `\brief` above one of the comment blocks. This brief section ends at the end of the paragraph and any further paragraphs are the detailed descriptions.

```
/*! \brief brief documentation.
 *      brief documentation.
 *
 *      detailed documentation.
 */
```

- By setting **JAVADOC\_AUTOBRIEF** to **yes**, the brief description will only last until the first dot followed by a space or new line. Consequentially limiting the brief description to a single sentence.

```
/** Brief documentation. Detailed documentation continues
 * from here.
 */
```

This can also be used with the above mentioned three-slash comment blocks (///).

- The third option is to use a special C++ style comment, ensuring this does not span more than one line.

```
/// Brief documentation.
/** Detailed documentation. */
```

or

```
///! Brief documentation.

///! Detailed documentation ///! starts here
```

The blank line in the above example is required to separate the brief description and the detailed description, and **JAVADOC\_AUTOBRIEF** must be set to **no**.

Examples of how a documented piece of C++ code using the Qt style can be found on the [Doxygen documentation website](#)

It is also possible to have the documentation after members of a file, struct, union, class, or enum. To do this add a < marker in the comment block.\!

```
int var; /*!< detailed description after the member */
```

Or in a Qt style as:

```
int var; /**< detailed description after the member */
```

or

```
int var; //!< detailed description after the member
//!<
```

or

```
int var; ///< detailed description after the member
///<
```

For brief descriptions after a member use:

```
int var; //!< brief description after the member
```

or

```
int var; ///< brief description after the member
```

Examples of these and how the HTML is produced can be viewed on the [Doxygen documentation website](#)

### Documentation at other places

While it is preferable to place documentation in front of the code it is documenting, at times it is only possible to put it in a different location, especially if a file is to be documented; after all it is impossible to place the documentation in front of a file. This is best avoided unless it is absolutely necessary as it can lead to some duplication of information.

To do this it is important to have a structural command inside the documentation block. Structural commands start with a backslash (\) or an at-sign (@) for JavaDoc and are followed by one or more parameters.

```
/*! \class Test
    \brief A test class.

    A more detailed description of class.
*/
```

In the above example the command **\class** is used. This indicates that the comment block contains documentation for the class 'Test'. Others are:

- » **\struct**: document a C-struct
- » **\union**: document a union
- » **\enum**: document an enumeration type
- » **\fn**: document a function
- » **\var**: document a variable, typedef, or enum value
- » **\def**: document a #define
- » **\typedef**: document a type definition
- » **\file**: document a file
- » **\namespace**: document a namespace
- » **\package**: document a Java package
- » **\interface**: document an IDL interface

3. Next, the contents of a special documentation block is parsed before being written to the HTML and / Latex output directories. This includes:
  - a. Special commands are executed.
  - b. Any white space and asterisks (\*) are removed.
  - c. Blank lines are taken as new paragraphs.
  - d. Words are linked to their corresponding documentation. Where the word is preceded by a percent sign (%) the percent sign is removed and the word remains.
  - e. Where certain patterns are found in the text, links to members are created. Examples of this can be found on the [automatic link generation page](#) on the Doxygen documentation website.
  - f. When the documentation is for Latex, HTML tags are interpreted and converted to Latex equivalents. A list of supported HTML tags can be found on the [HTML commands page](#) on the Doxygen documentation website.

### 9.1.5. Resources

More information can be found on the Doxygen website.

## Appendix A. Appendix

### A.1. `mallopt`

`mallopt` is a library call that allows a program to change the behavior of the malloc memory allocator.

#### Example A.1. Allocator heuristics

An allocator has heuristics to determine long versus short lived objects. For the former, it attempts to allocate with `mmap`. For the later, it attempts to allocate with `sbrk`.

In order to override these heuristics, set `M_MMAP_THRESHOLD`.

In multi-threaded applications, the allocator creates multiple *arenas* in response to lock contention in existing arenas. This can improve the performance significantly for some multi-threaded applications at the cost of an increase in memory usage. To keep this under control, limit the number of arenas that can be created by using the `mallopt` interface.

The allocator has limits on the number of arenas it can create. For 32bit targets, it will create  $2 * \#$  core arenas; for 64bit targets, it will create  $8 * \#$  core arenas. `mallopt` allows the developer to override those limits.

#### Example A.2. `mallopt`

To ensure no more than eight arenas are created, issue the following library call:

```
mallopt (M_ARENA_MAX, 8);
```

The first argument for `mallopt` can be:

- » `M_MXFAST`
- » `M_TRIM_THRESHOLD`
- » `M_TOP_PAD`
- » `M_MMAP_THRESHOLD`
- » `M_MMAP_MAX`
- » `M_CHECK_ACTION`
- » `M_PERTURB`
- » `M_ARENA_TEST`
- » `M_ARENA_MAX`

Specific definitions for the above can be found at <http://www.makelinux.net/man/3/M/mallopt>.

### `malloc_trim`

**malloc\_trim** is a library call that requests the allocator return any unused memory back to the operating system. This is normally automatic when an object is freed. However, in some cases when freeing small objects, **glibc** might not immediately release the memory back to the operating system. It does this so that the free memory can be used to satisfy upcoming memory allocation requests as it is expensive to allocate from and release memory back to the operating system.

### **malloc\_stats**

**malloc\_stats** is used to dump information about the allocator's internal state to **stderr**. Using **mallinfo** is similar to this, but it places the state into a structure instead.

## **Further Information**

More information on **mallopt** can be found at <http://www.makelinux.net/man/3/M/mallopt> and [http://www.gnu.org/software/libc/manual/html\\_node/Malloc-Tunable-Parameters.html](http://www.gnu.org/software/libc/manual/html_node/Malloc-Tunable-Parameters.html).

## Appendix B. Revision History

<b>Revision 2-56</b>	<b>Tue Jul 6 2015</b>	<b>Robert Krátký</b>
Release of the Developer Guide for Red Hat Enterprise Linux 6.7		
<b>Revision 2-55</b>	<b>Wed Apr 15 2015</b>	<b>Robert Krátký</b>
Release of the Developer Guide for Red Hat Enterprise Linux 6.7 Beta		
<b>Revision 2-54</b>	<b>Tue Dec 16 2014</b>	<b>Robert Krátký</b>
Update to sort order on the Red Hat Customer Portal.		
<b>Revision 2-52</b>	<b>Wed Nov 11 2014</b>	<b>Robert Krátký</b>
Re-release for RHSCL 1.2 and DTS 3.0.		
<b>Revision 2-51</b>	<b>Fri Oct 10 2014</b>	<b>Robert Krátký</b>
Release of the Developer Guide for Red Hat Enterprise Linux 6.6
